

The drift diffusion model of decision formation

Bob Wilson

University of Arizona

Georgia Institute of Technology

Outline

- The basic drift diffusion model
 - Interrogation paradigm
 - Free response paradigm
- Neural implementation of the DDM
- Value-based drift diffusion model
 - Relation to softmax
 - Differentiating drift vs threshold changes using response times
- An example: what drives random exploration?
- Summary

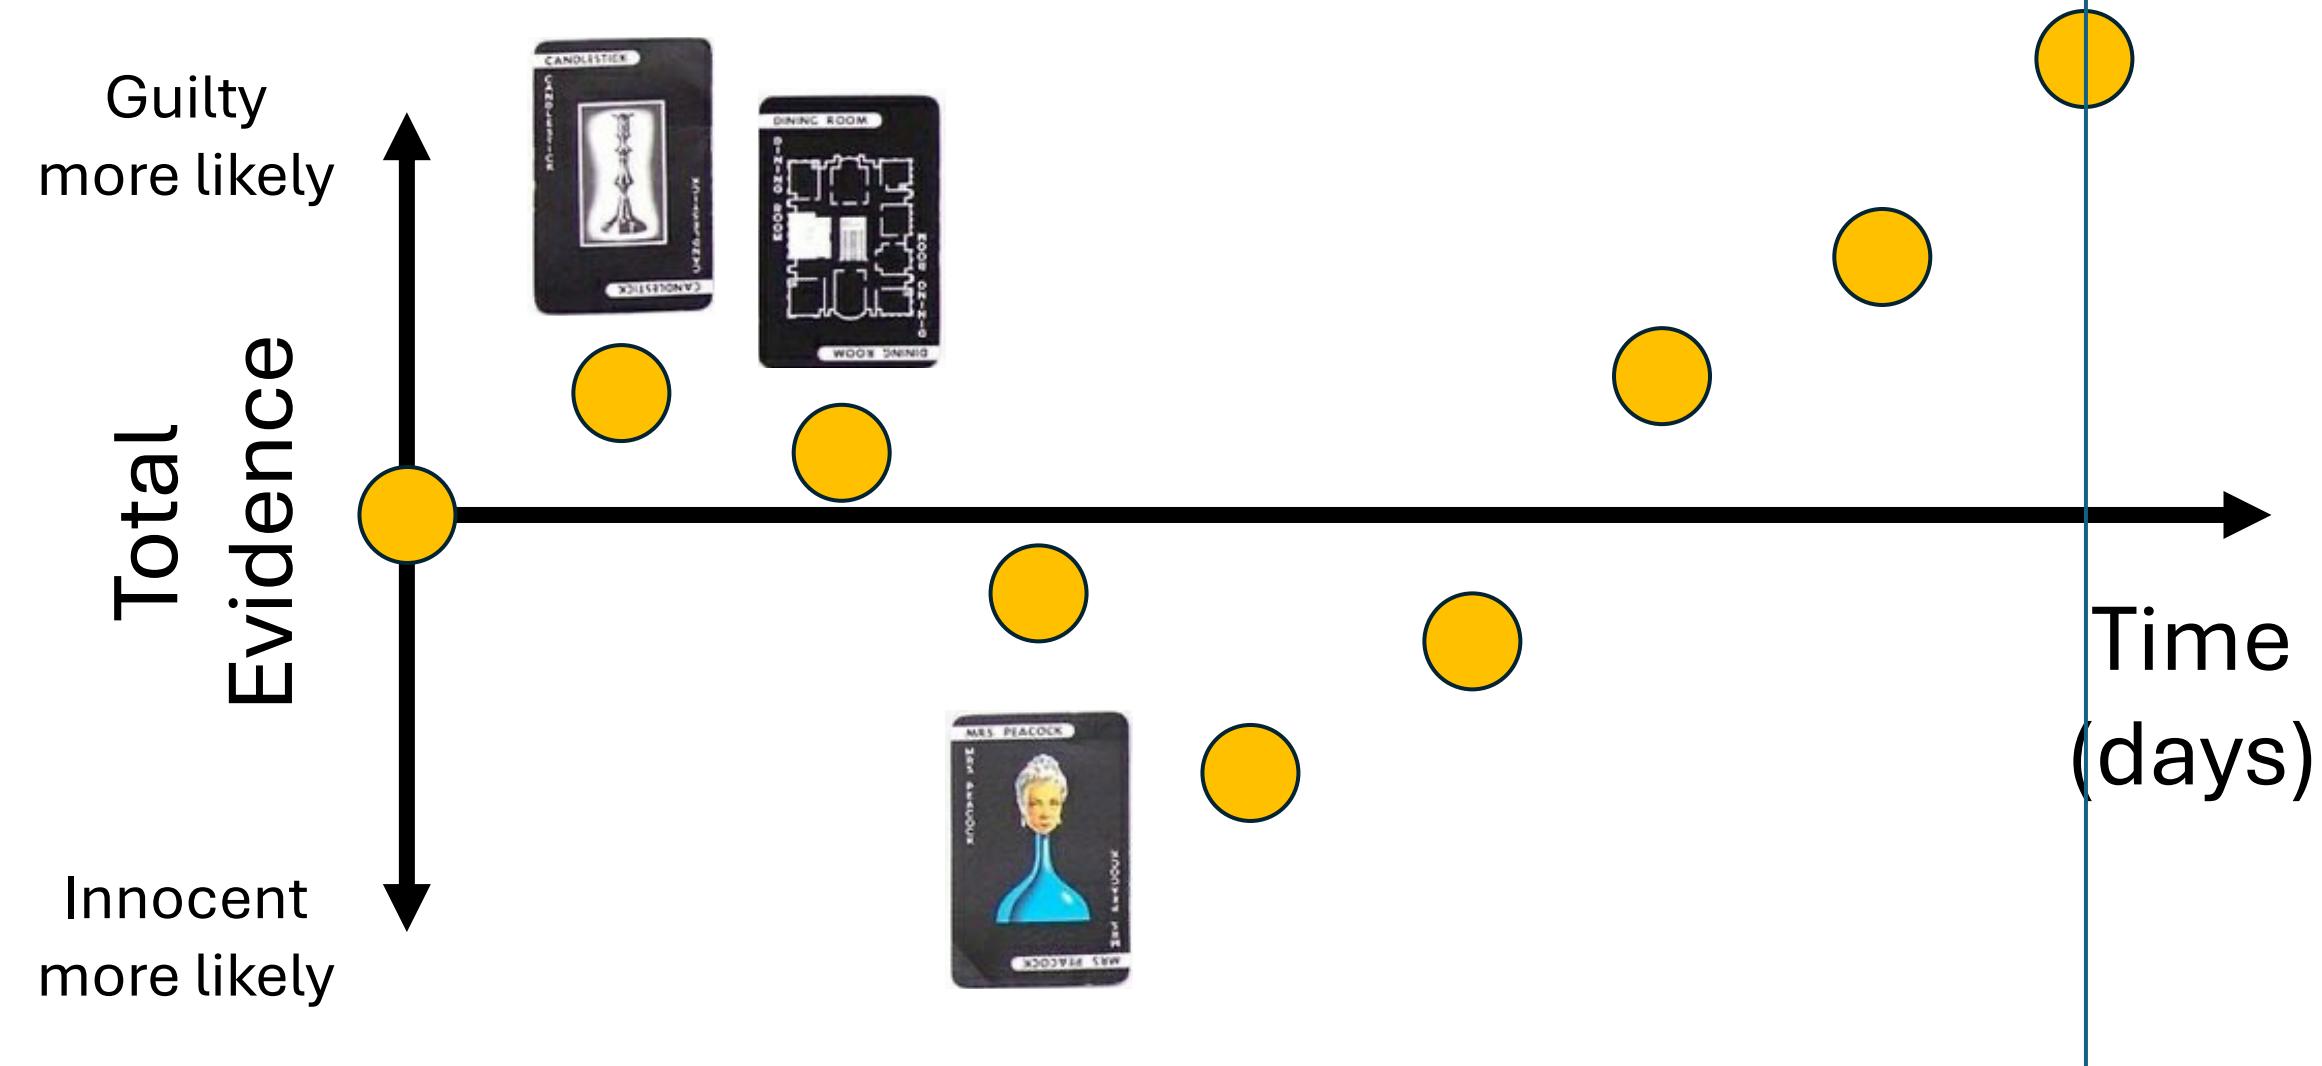

*The drift diffusion model
interrogation paradigm*

Jury duty ... deciding on guilt or innocence

- Evidence is presented sequentially over the course of the trial
- As each piece of evidence is presented your opinion as to guilt or innocence will evolve over time
- This can be represented graphically ...

Integrating evidence over time

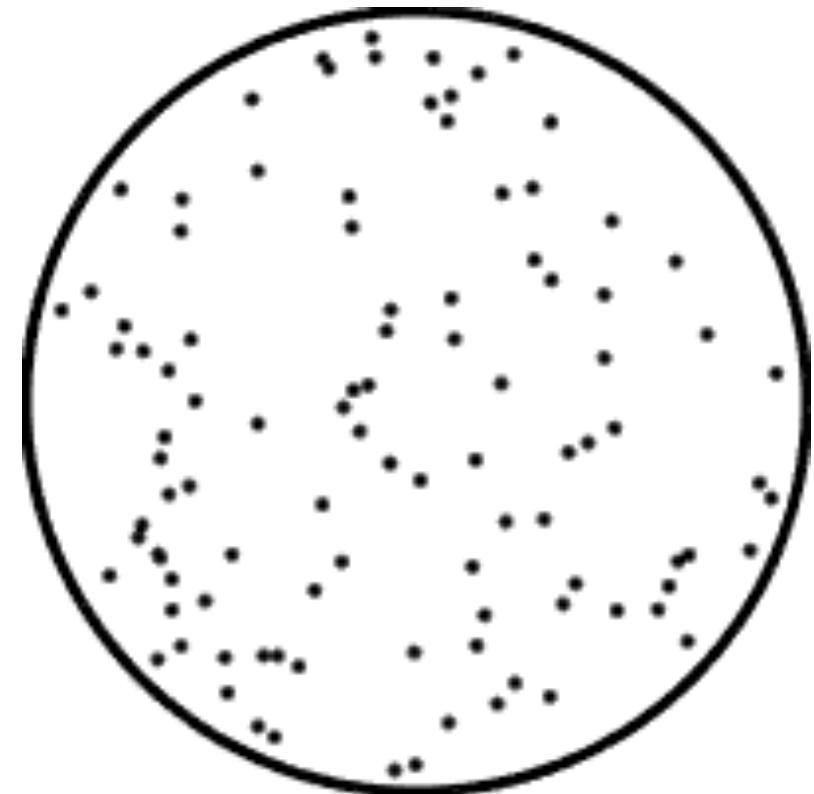

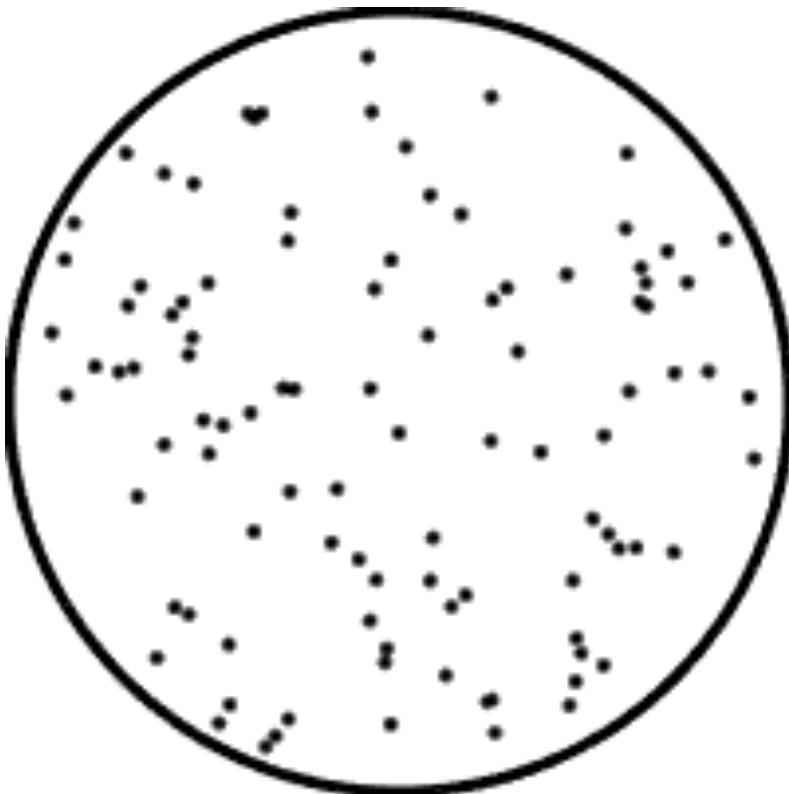

Integrating neural evidence

- The drift diffusion model assumes a similar process of evidence plays out on a much faster time scale to make rapid fire decisions
- The “evidence” is neural firing in favor of one option or another
- The classic example of this is the perceptual decision about a moving dot stimulus ...

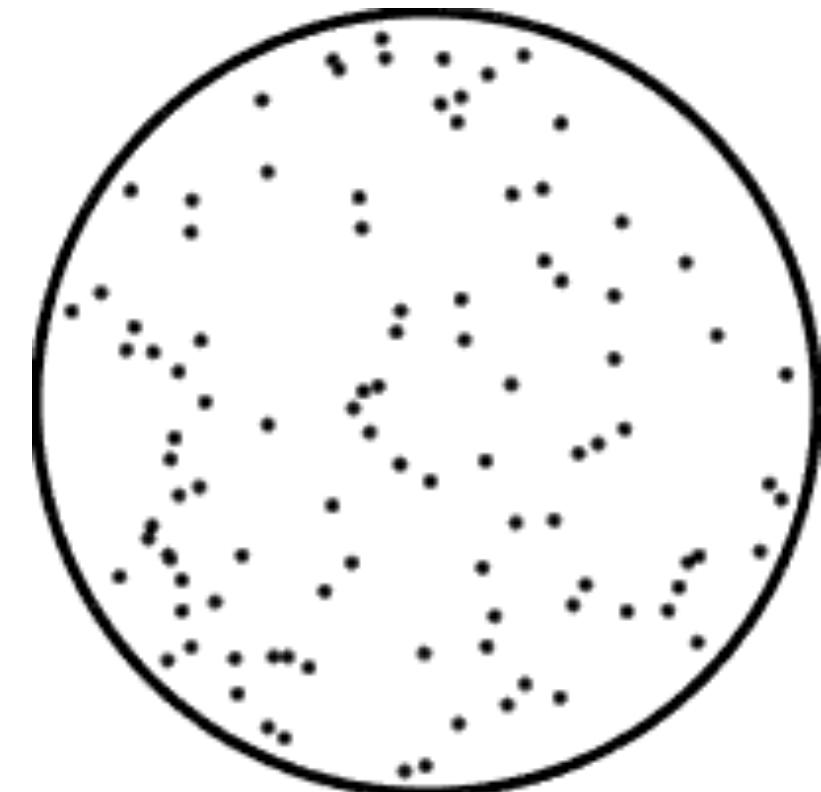

Moving dots ...

- Which way are most of the the dots moving?

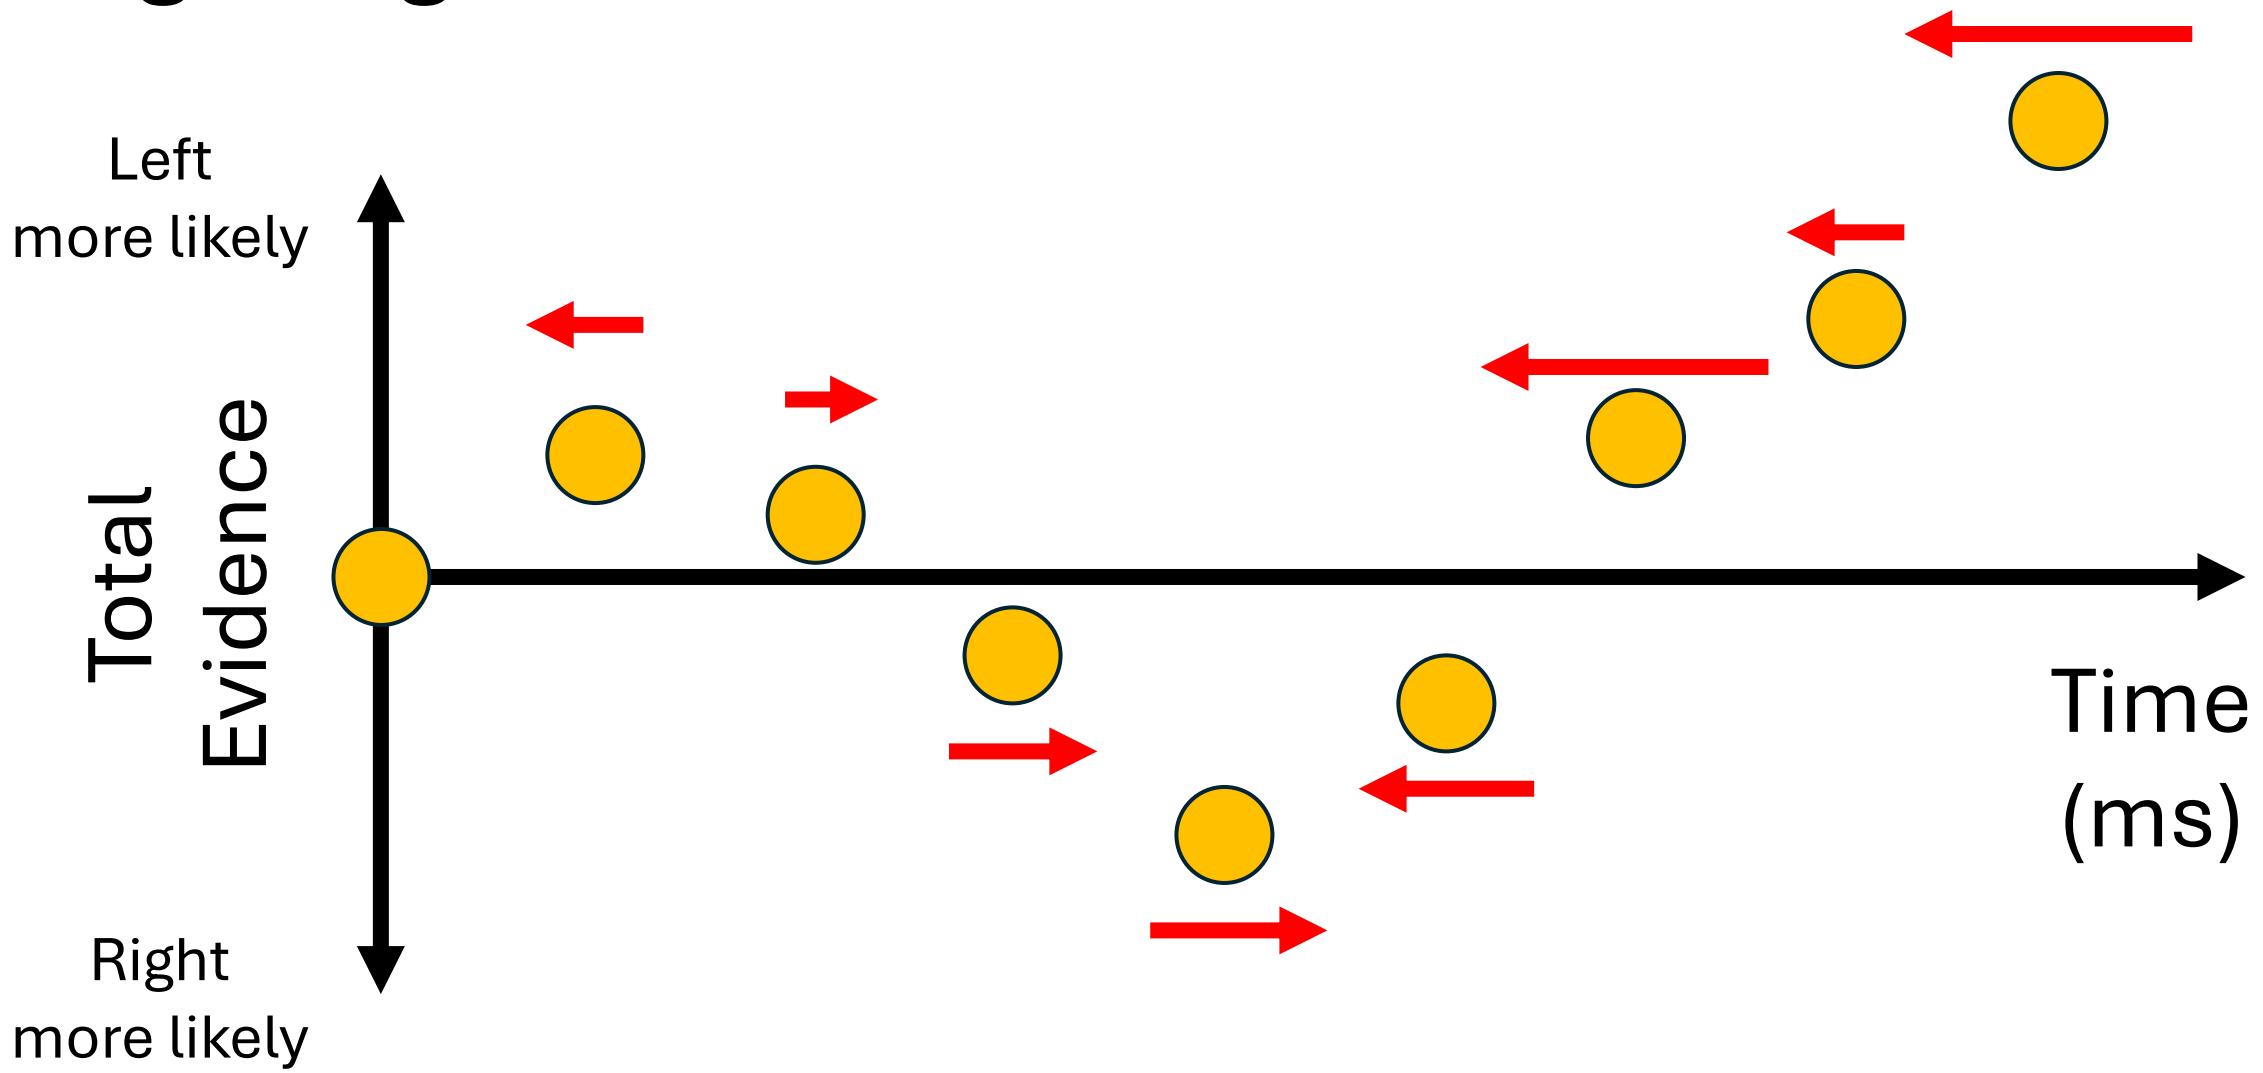

Moving dots ...

- Each dot moves randomly left or right and can change from frame to frame of the movie
- More dots move in one direction
- To make the correct decision need to integrate the evidence (left or right) over time

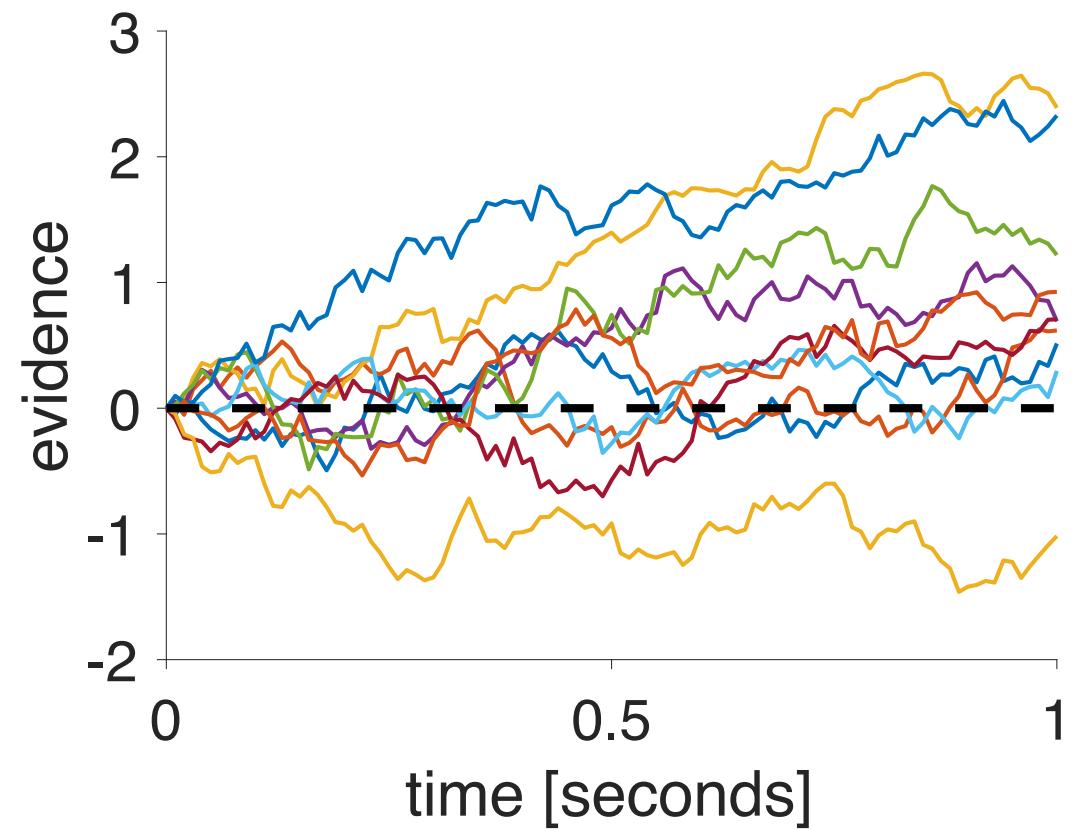

Integrating evidence over time

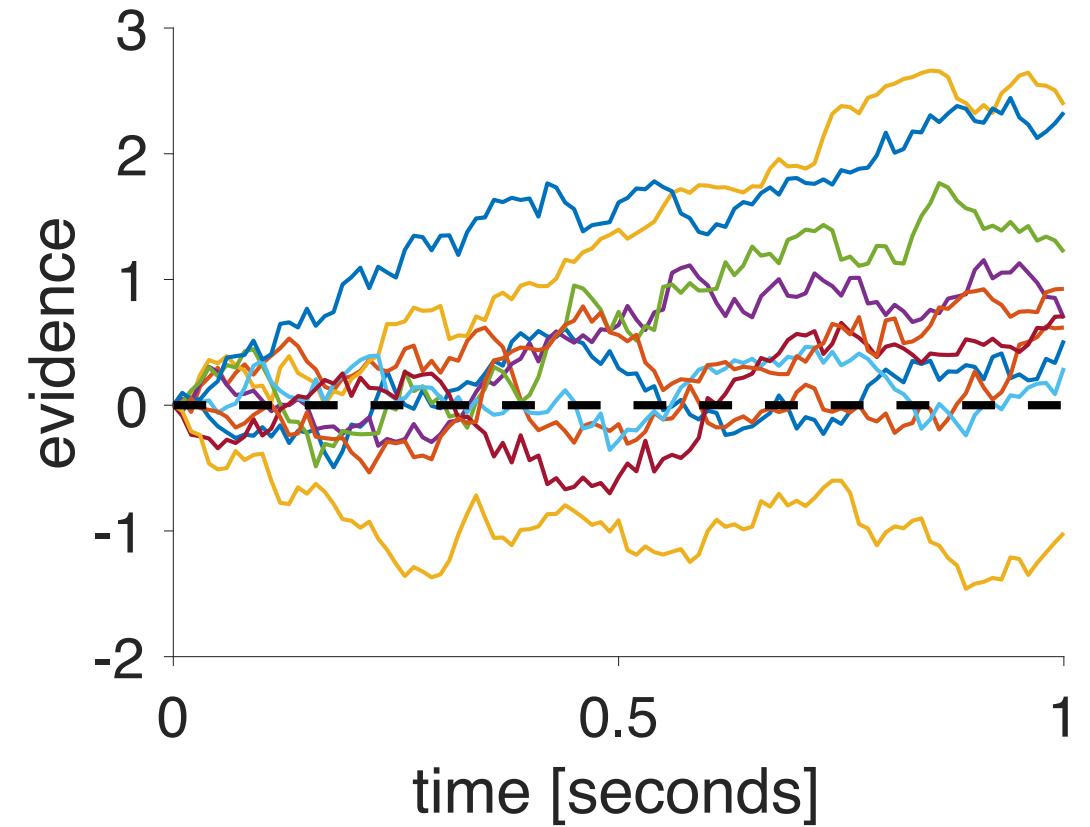

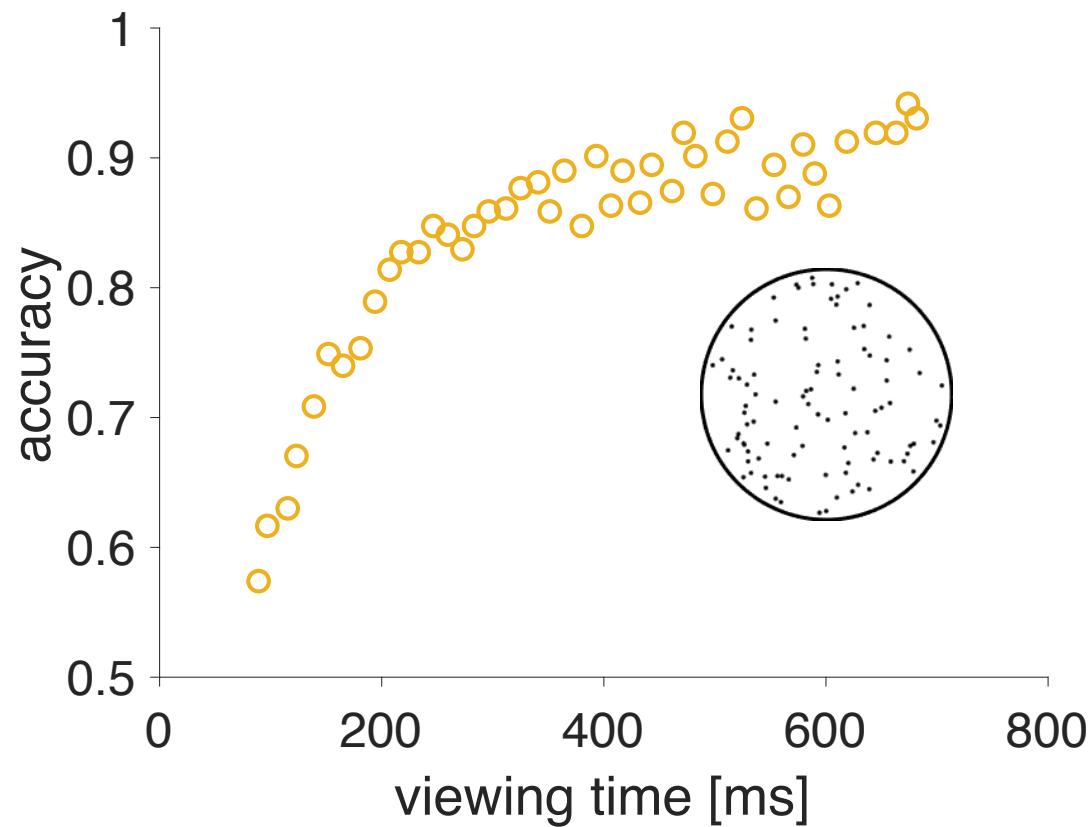

Evidence contains both signal and noise ...

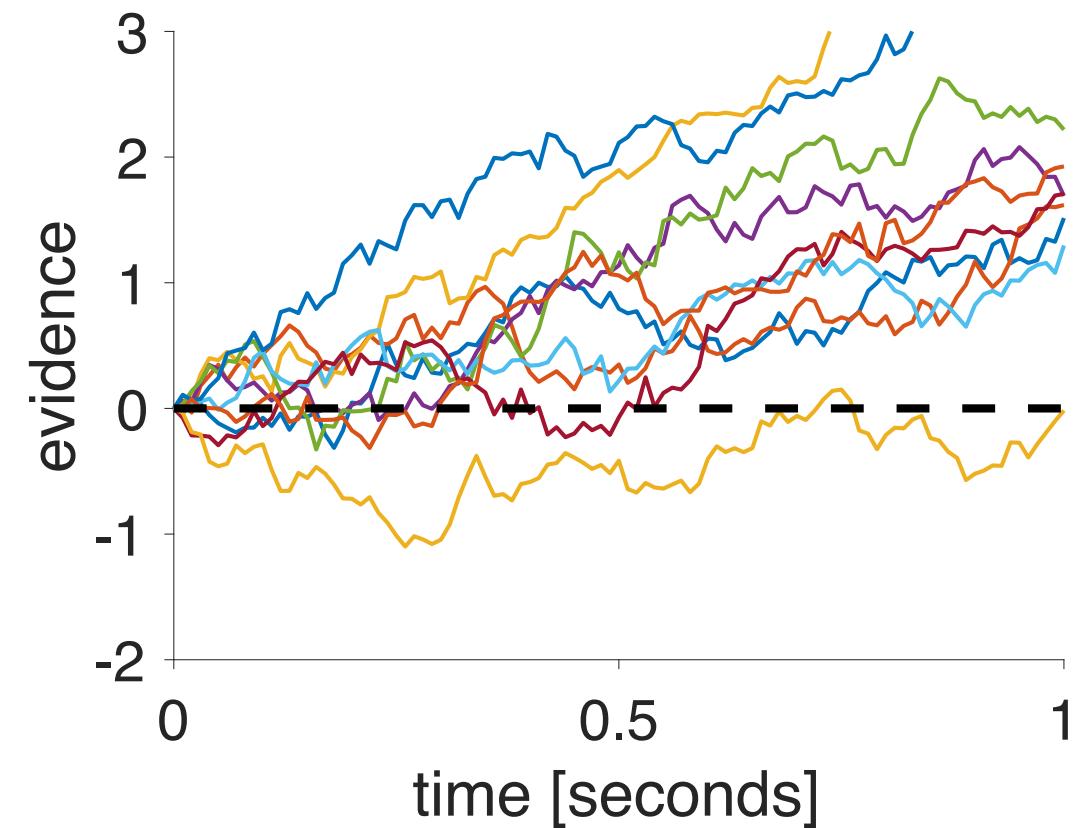

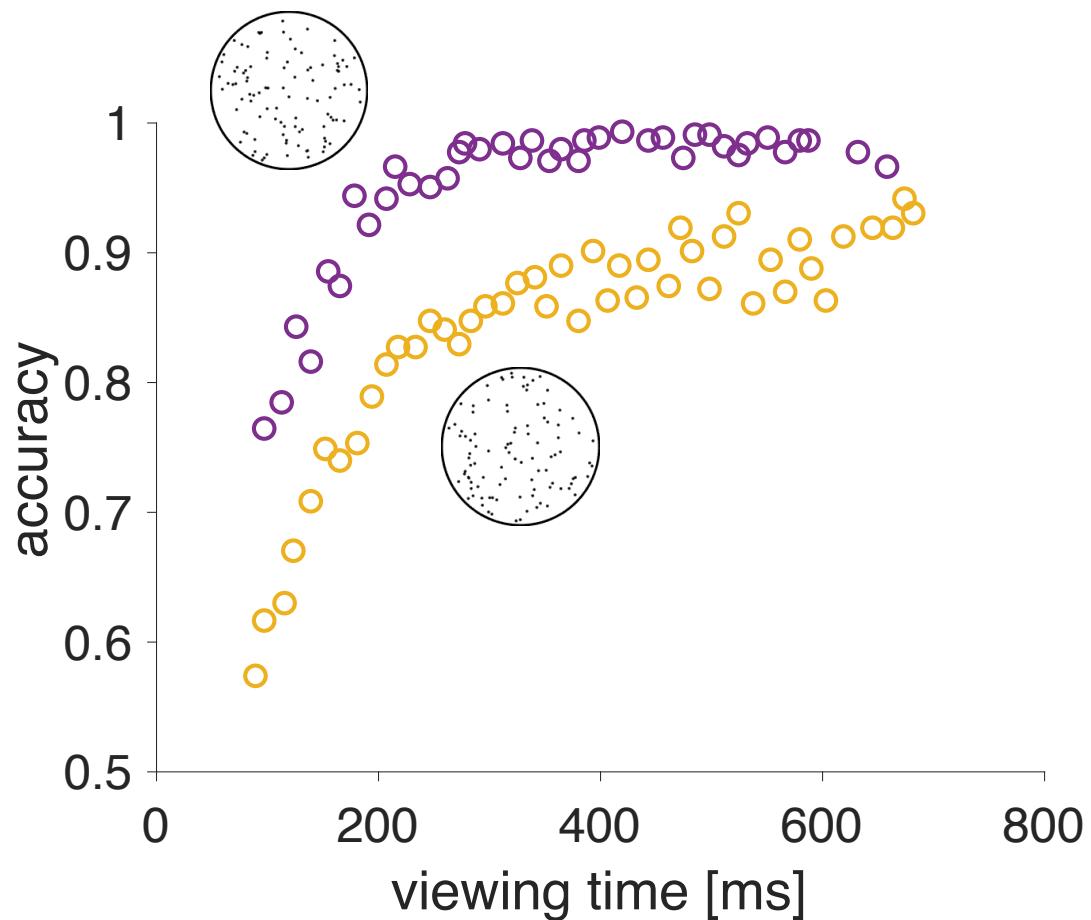

- On average, evidence points in the correct direction, **signal**
- But randomness in the stimulus and the brain (e.g. random spiking) causes **noise**
- As a result of noise, the accumulated evidence **drifts** (signal) and **diffuses** (noise) in the correct direction
- Because noise is random, every trial has a different trajectory

Increasing viewing time increases accuracy

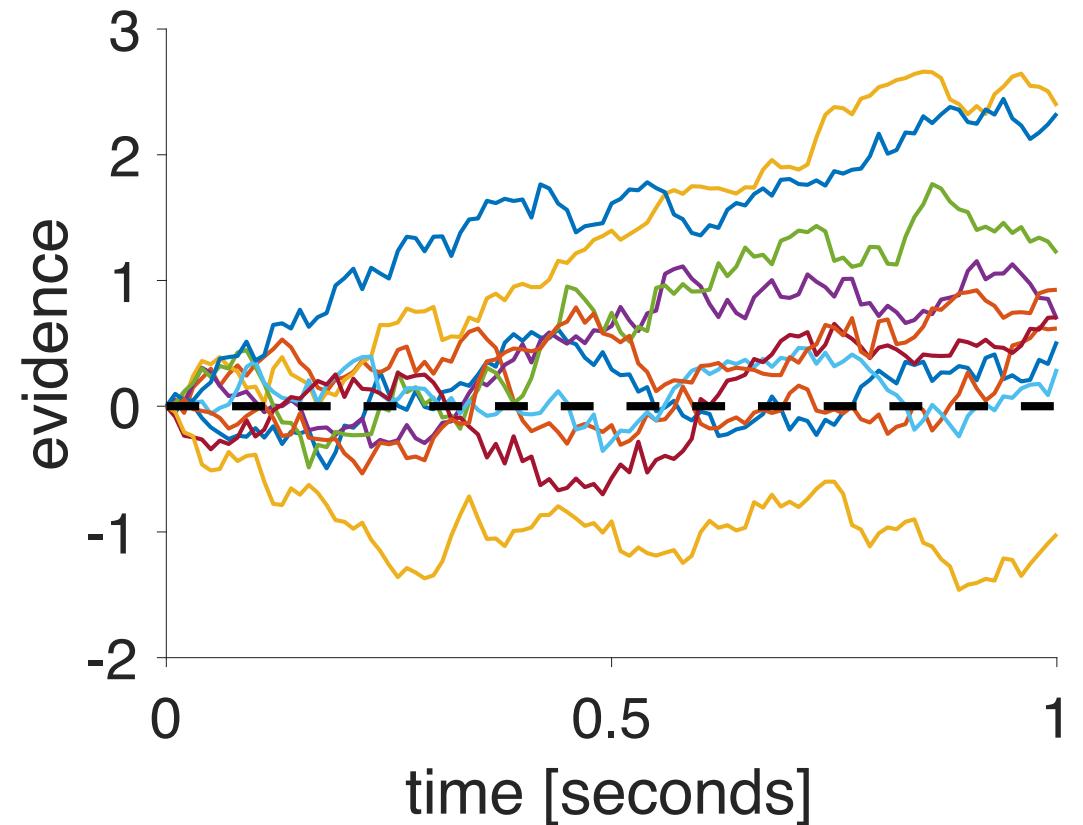

Increasing drift rate increases accuracy

DDM in the interrogation paradigm (jury duty)

- Evidence presented sequentially over time
- Evidence is integrated over time
- Decision is made after all evidence is presented
- Accuracy increases with viewing time

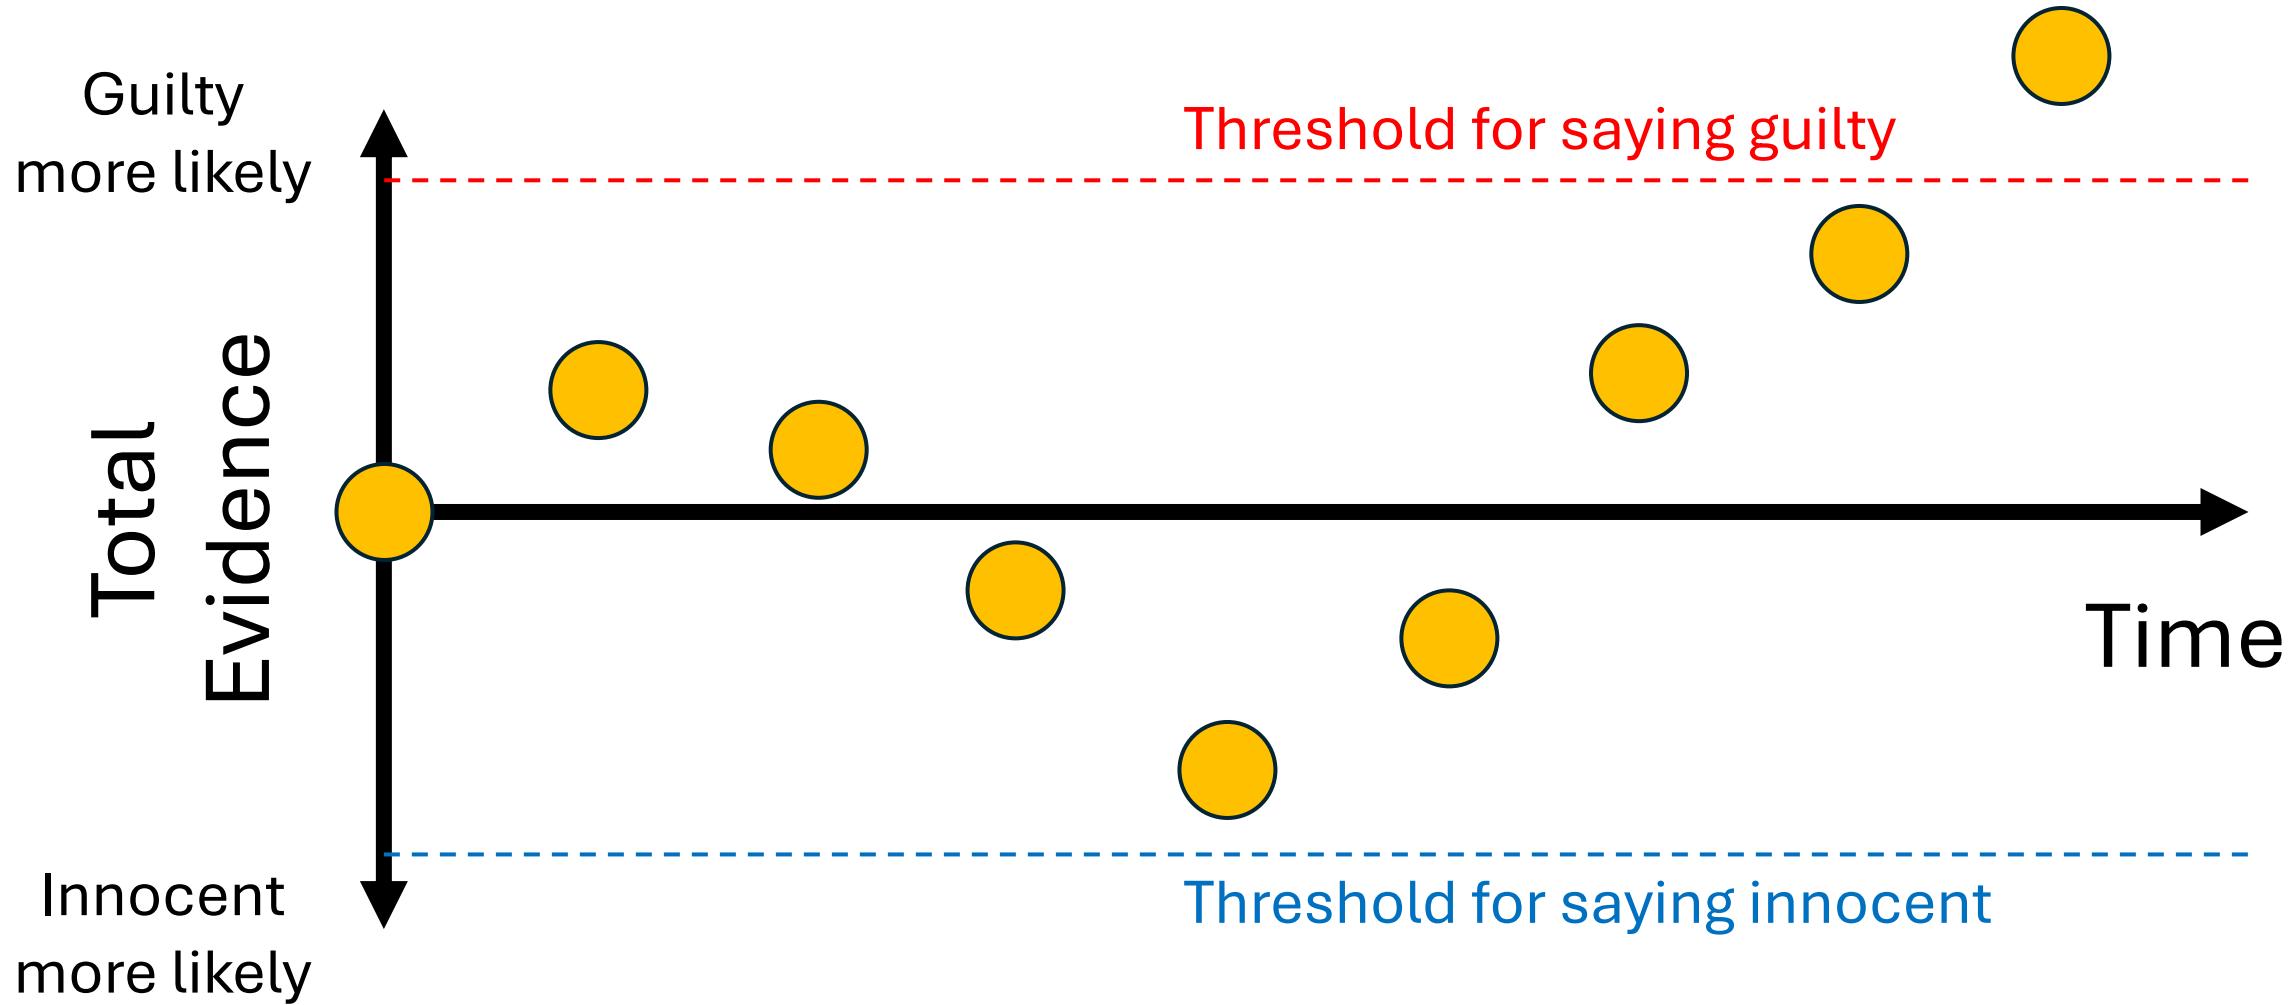

*The drift diffusion model
free response paradigm*

What if you are the investigator?

- So far considered case where evidence is presented and decision is made at the end
 - Like jury duty
- What about the case where you also decide when to stop collecting evidence?
 - Like an investigator
- Investigators stop investigating when they have enough evidence to convict, when the total evidence passes a **threshold**

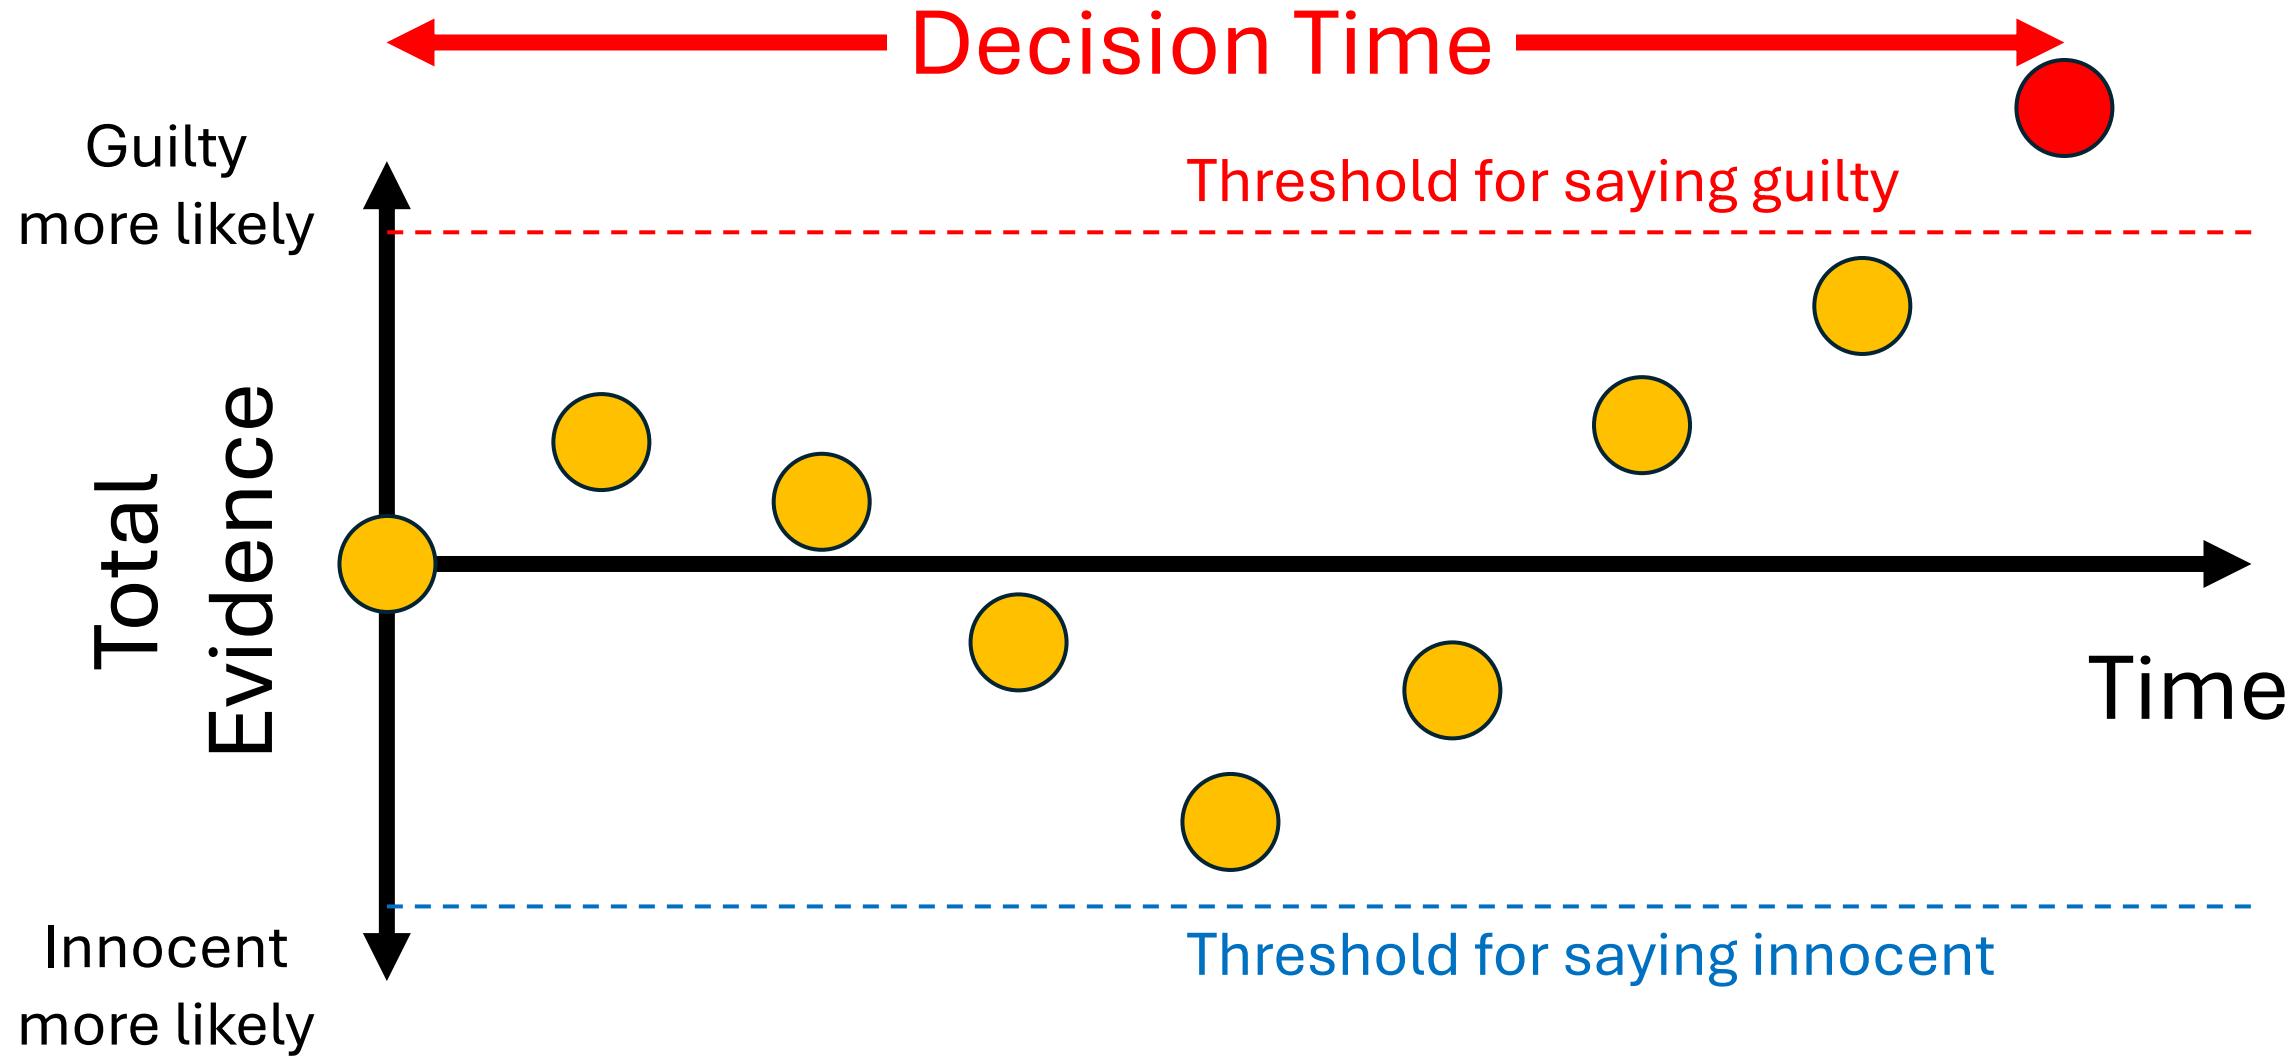

The decision thresholds ...

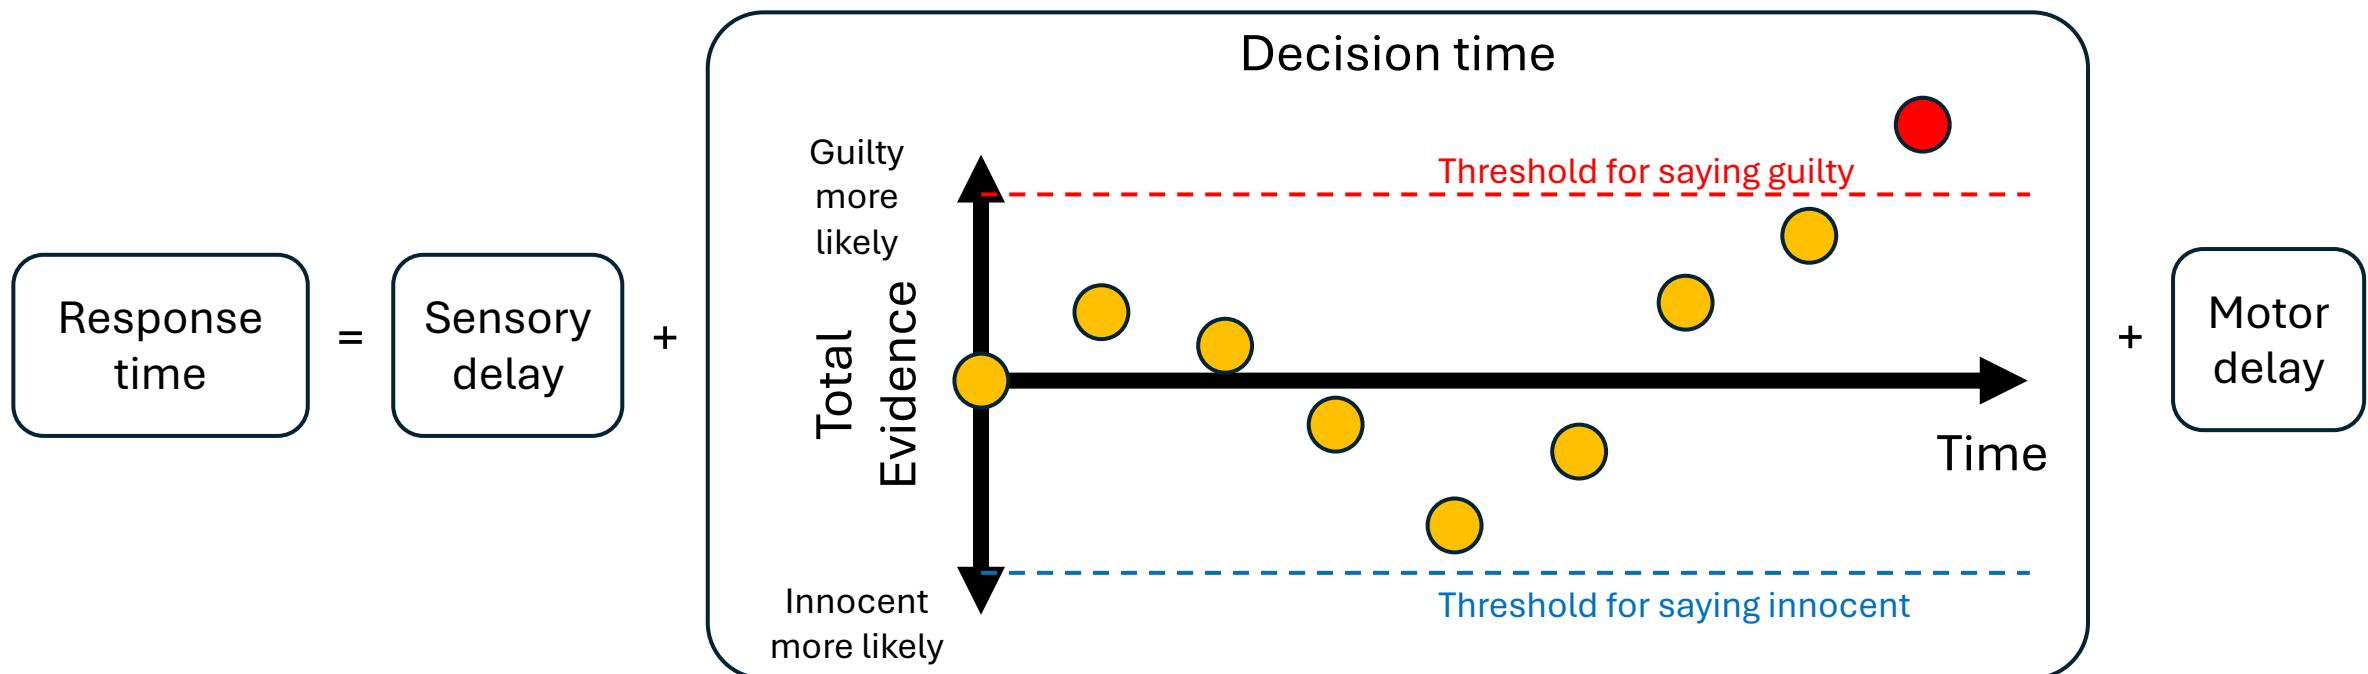

Decision = guilty

The decision thresholds ...

DDM in the free response paradigm

- Models choices AND decision times
- Transform decision times to response times by accounting for delays

$$RT = T_0 + DT$$

T_0 = Non-decision time

Some math ...

- A stochastic differential equation for the evidence ...

$$dE(t) = Adt + cdW(t)$$

Change in
evidence at
time t

Drift (signal)

Random
noise

Drift rate

Noise standard
deviation

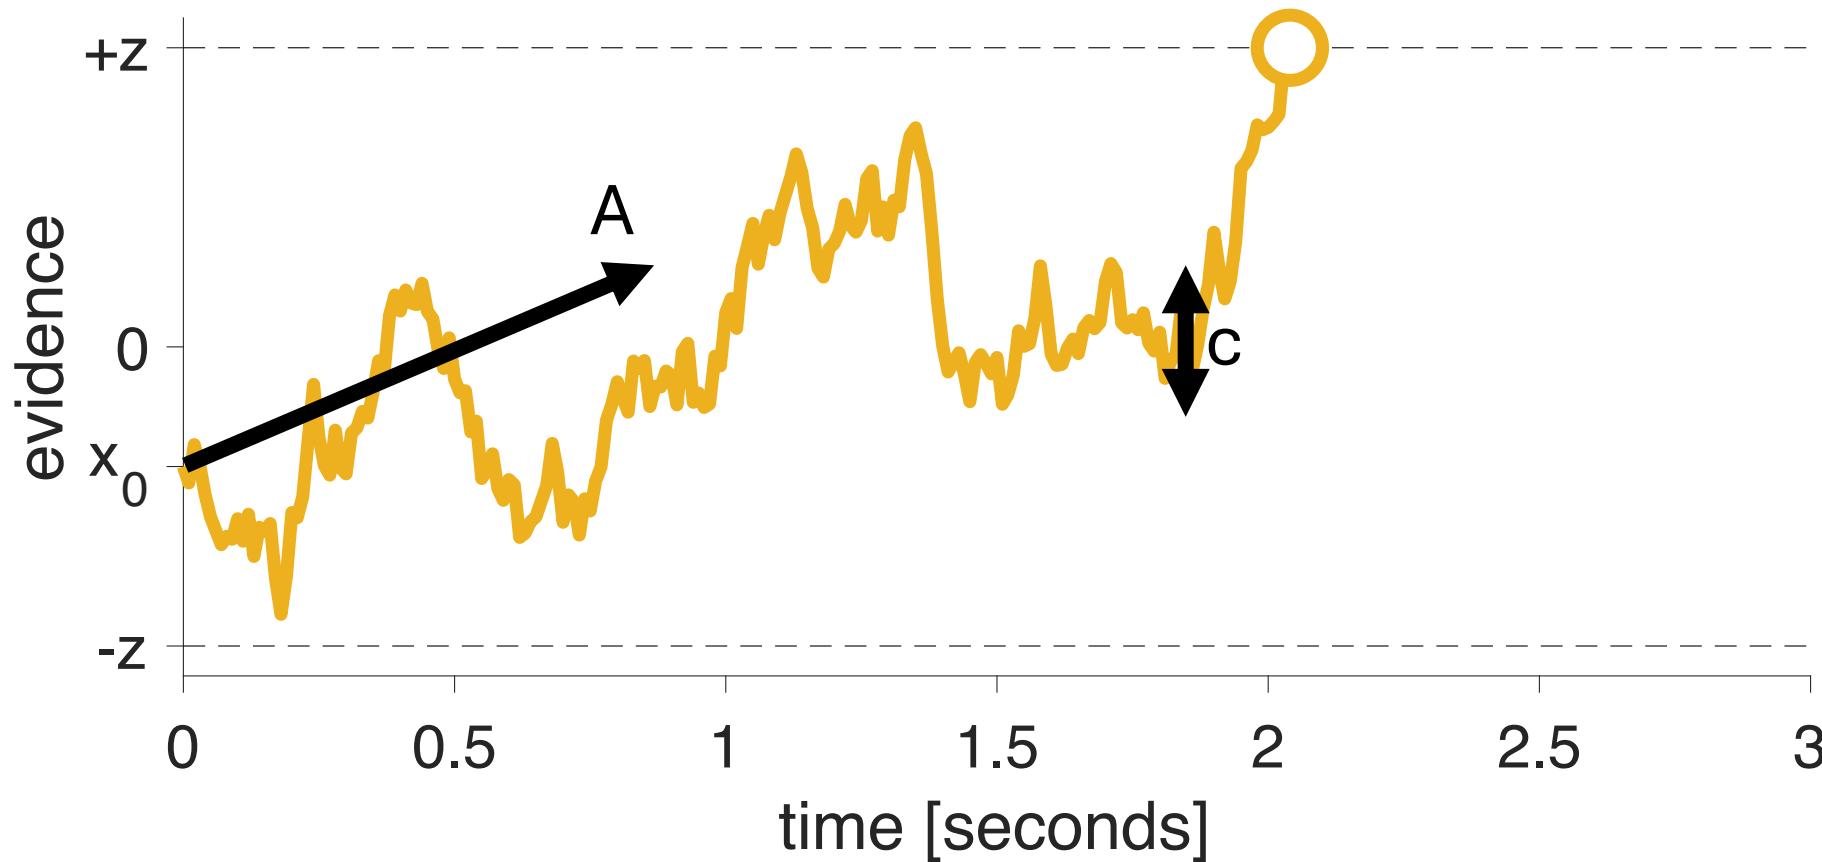

- Evidence is integrated over time, starting at initial bias x_0
- Decision is made when evidence crosses threshold at $+z$ or $-z$, which gives choice and decision time, DT
- Response time is decision time + non-decision time

$$RT = T_0 + DT$$

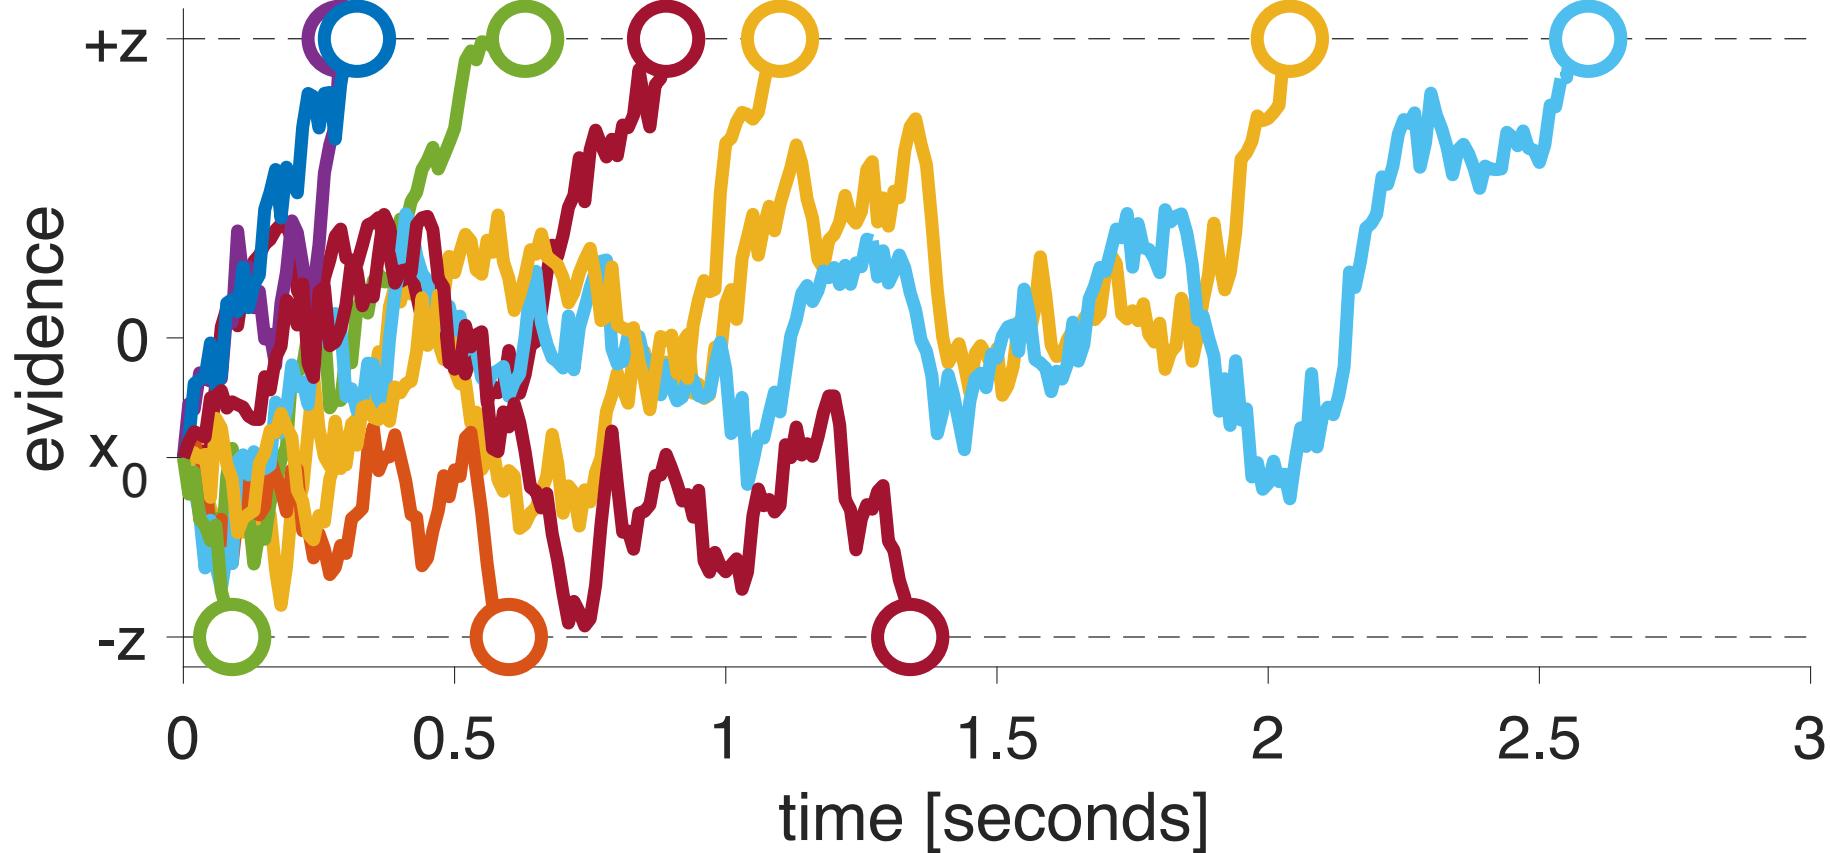

Parameters

- Non-decision time T_0
- Starting point (initial bias) x_0
- Drift rate (signal-to-noise ratio) A
- Threshold z
- Noise standard deviation C
 - In practice set to 1 and interpret drift rate as a signal-to-noise ratio

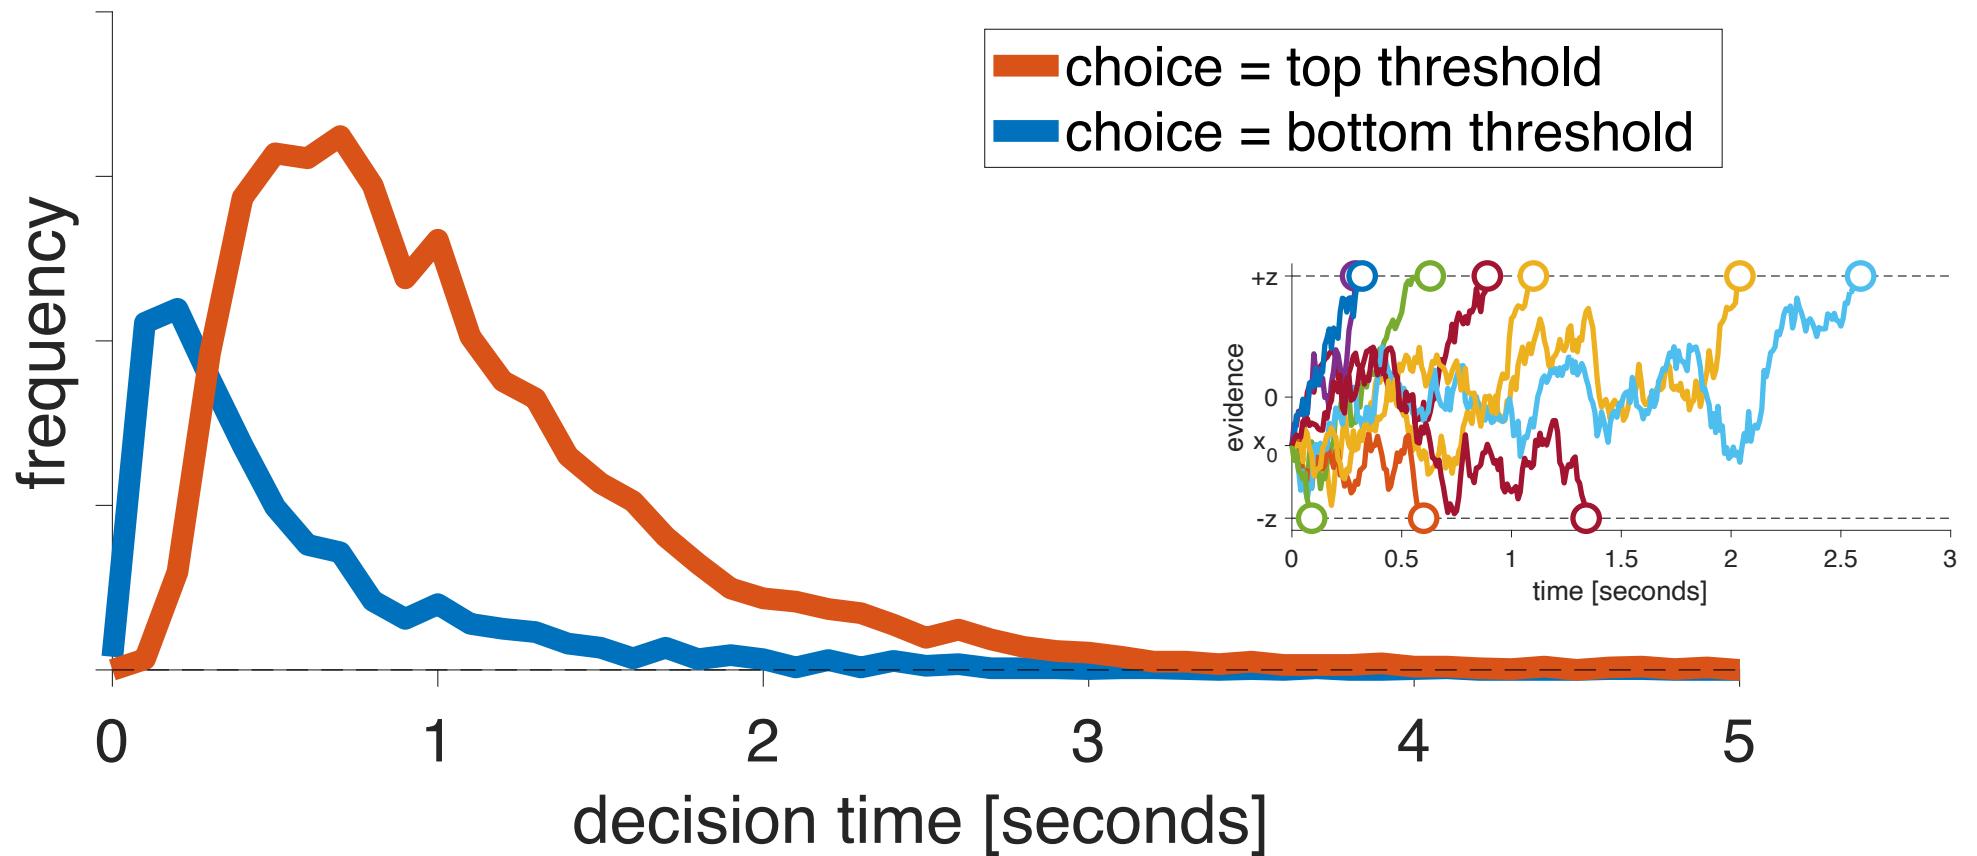

Classic DDM picture ...

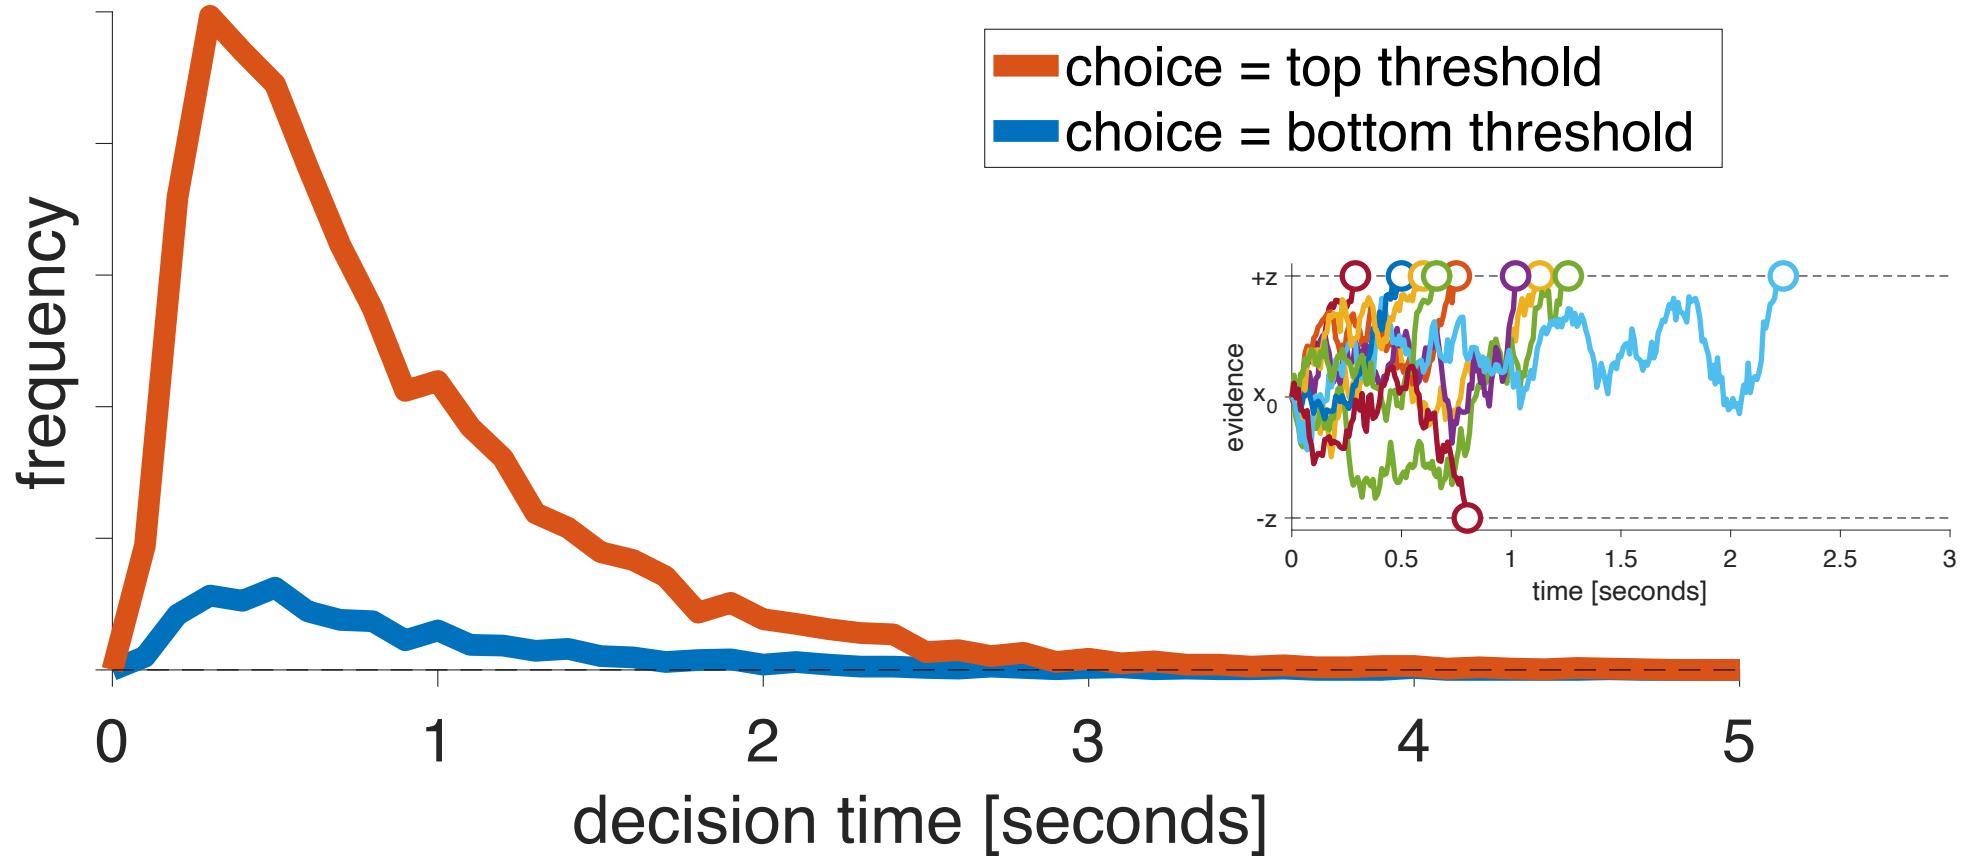

Noise causes variability in choices and decision times

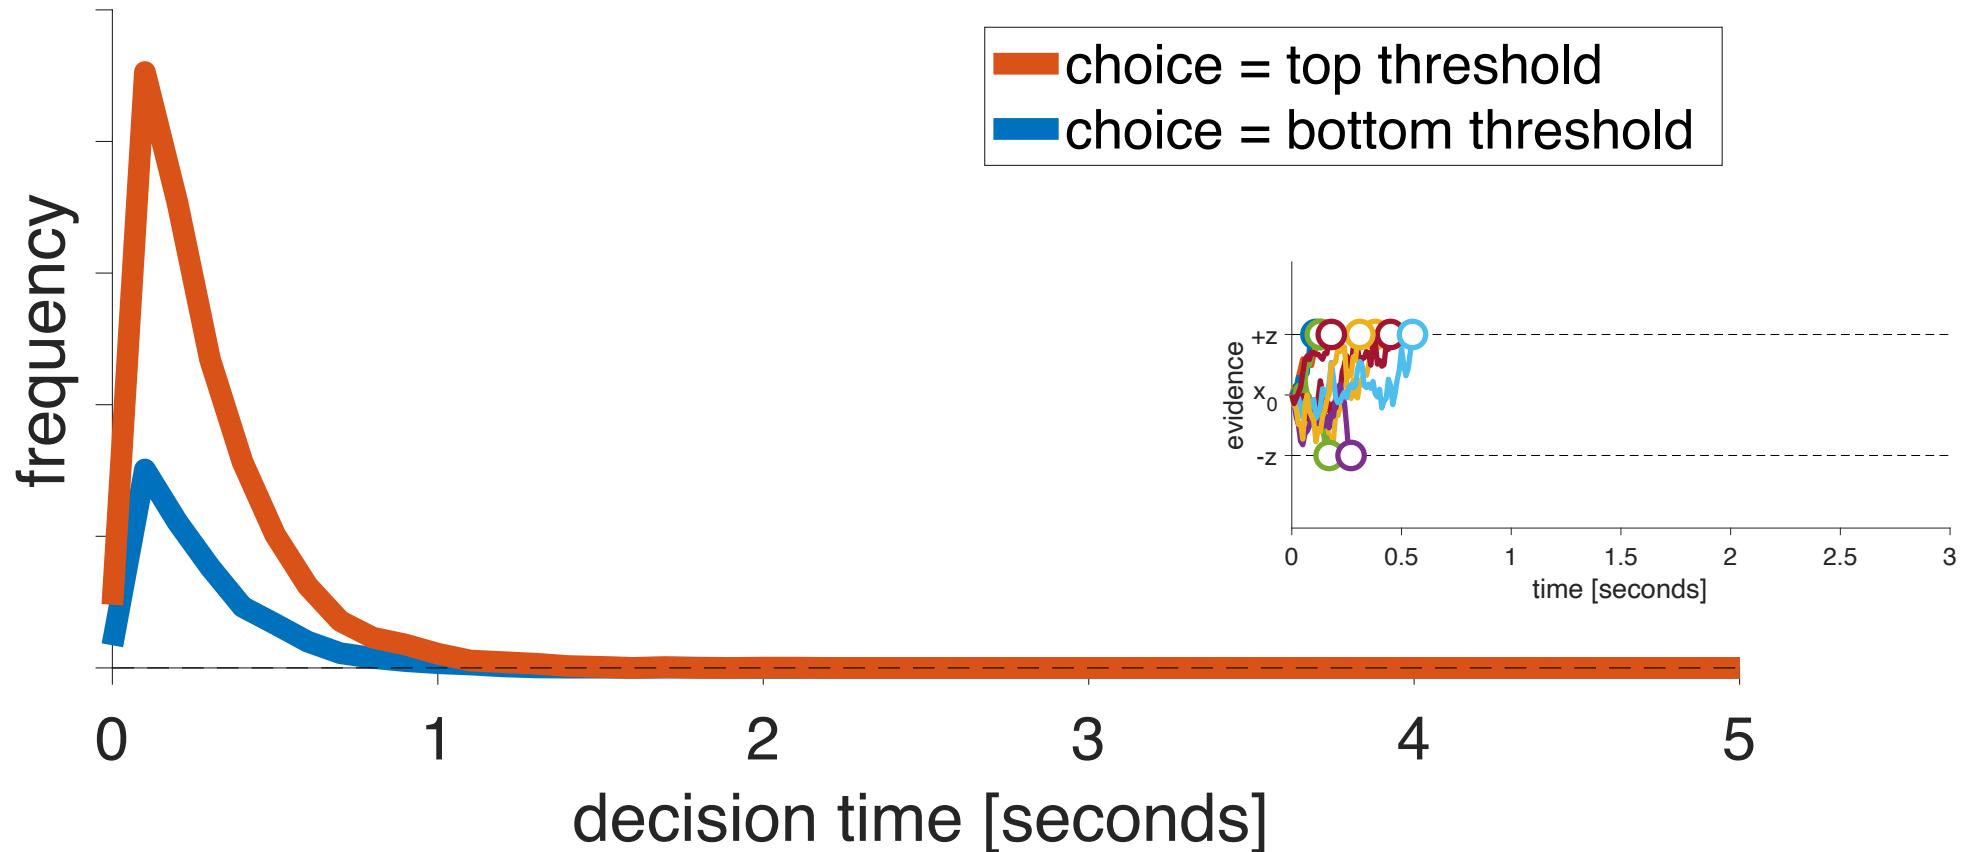

Choice and response time distributions

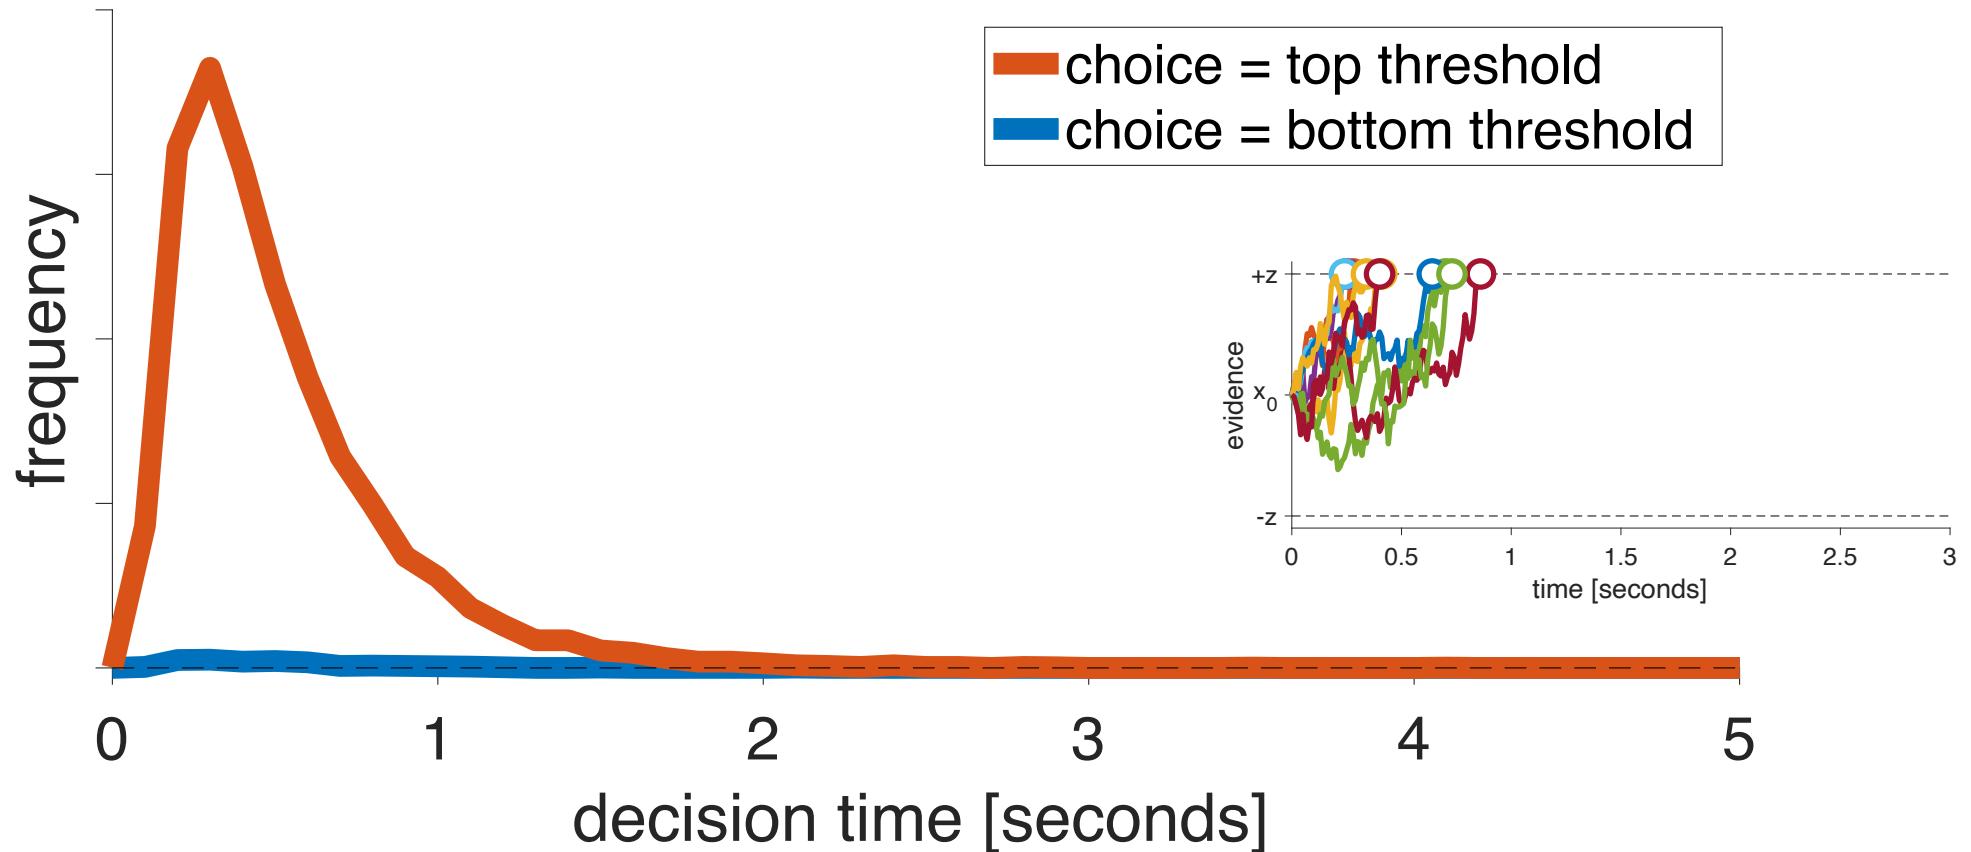

Changing starting point => changes type and amount of errors

Lower threshold
=> faster, less accurate

Higher drift
=> faster, more accurate

Analytic expressions for mean accuracy and response time

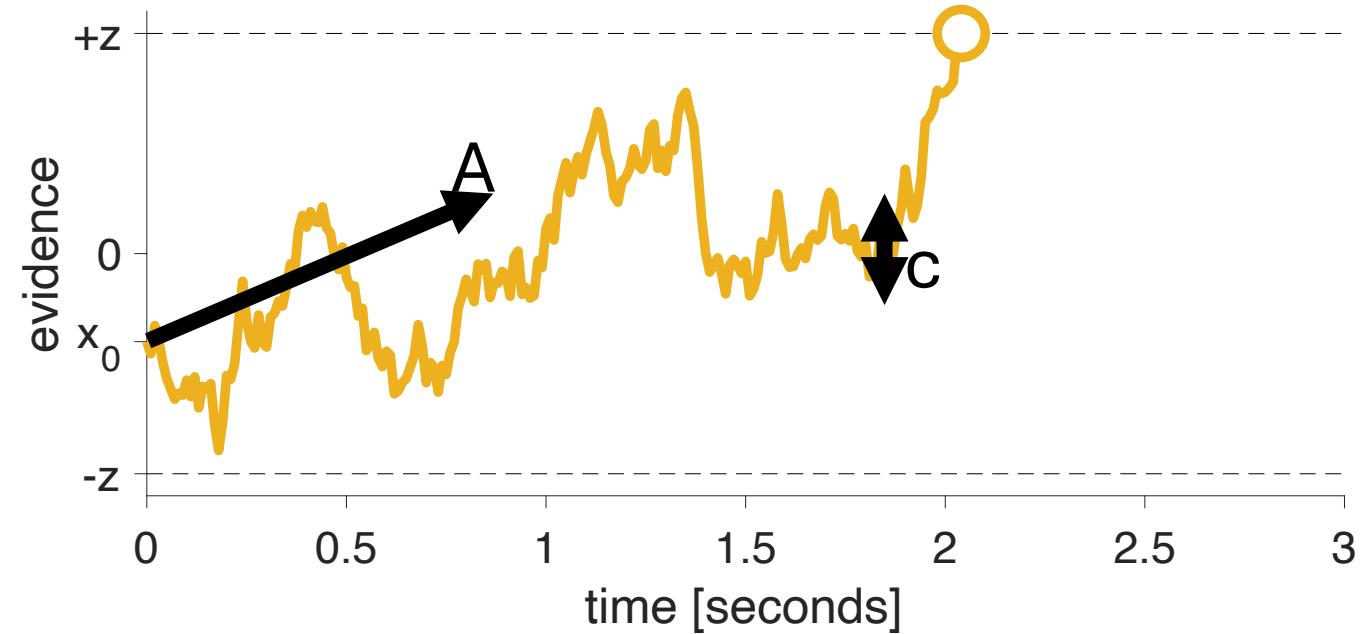

$$p(\text{choice} = \text{left}) = \frac{1}{1 + \exp(2zA)} - \frac{1 - \exp(-2x_0A)}{\exp(2zA) - \exp(-2zA)}$$

$$RT = T_0 + \frac{z}{A} \tanh(zA) + \frac{z}{A} \frac{2(1 - \exp(-2x_0A))}{\exp(2zA) - \exp(-2zA)} - \frac{x_0}{A}$$

- Can be handy for visualization of results
- Can also be useful for analysis of reward rate – i.e. reward per unit time
- Also – coming up – equates to softmax equation for value-based DDMs

DDM free response paradigm ...

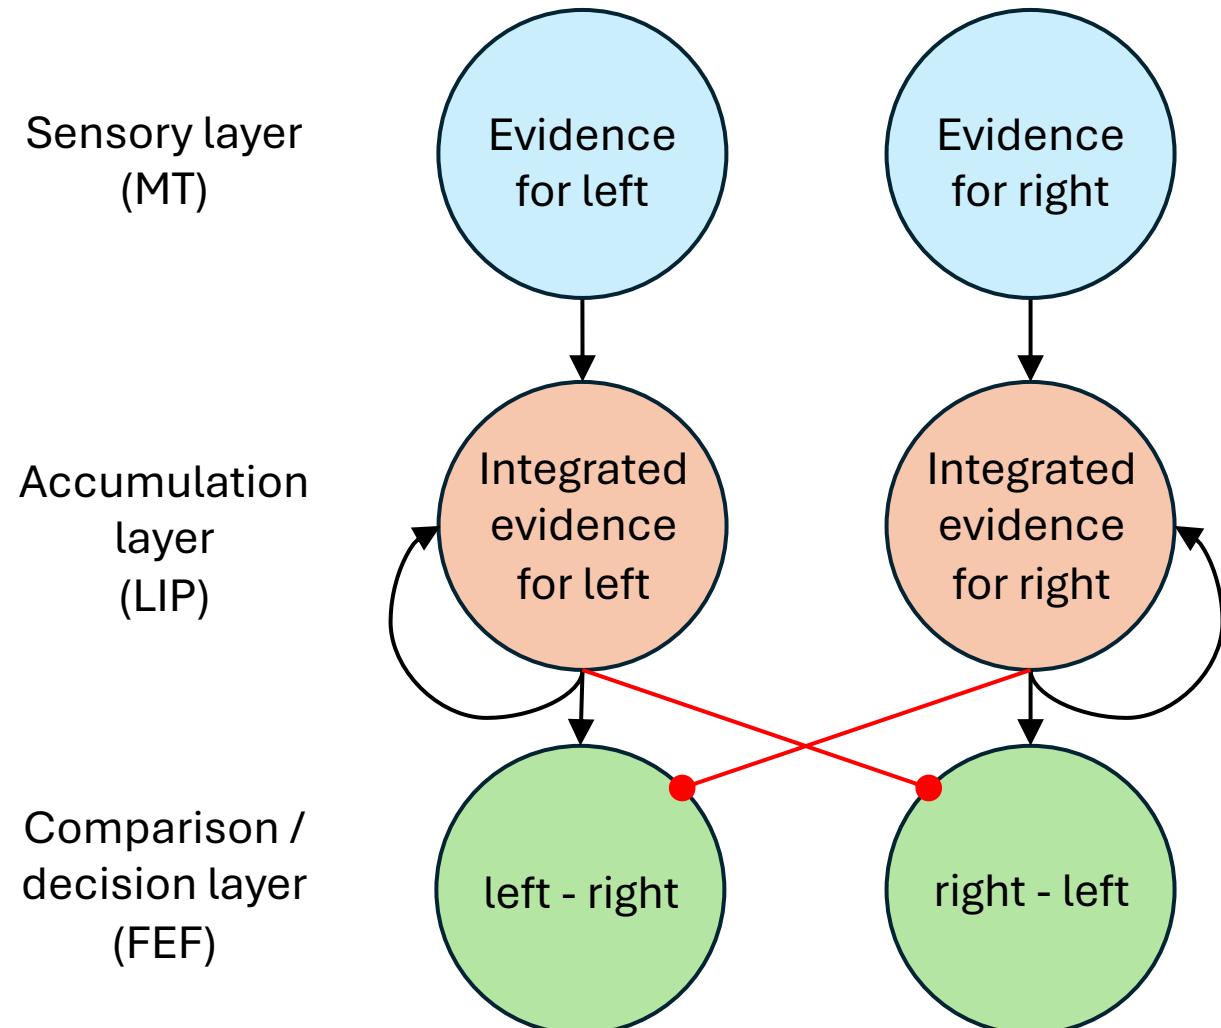

- Integrate evidence to threshold
- Which threshold crossed determines choice
- When threshold crossed determines decision time

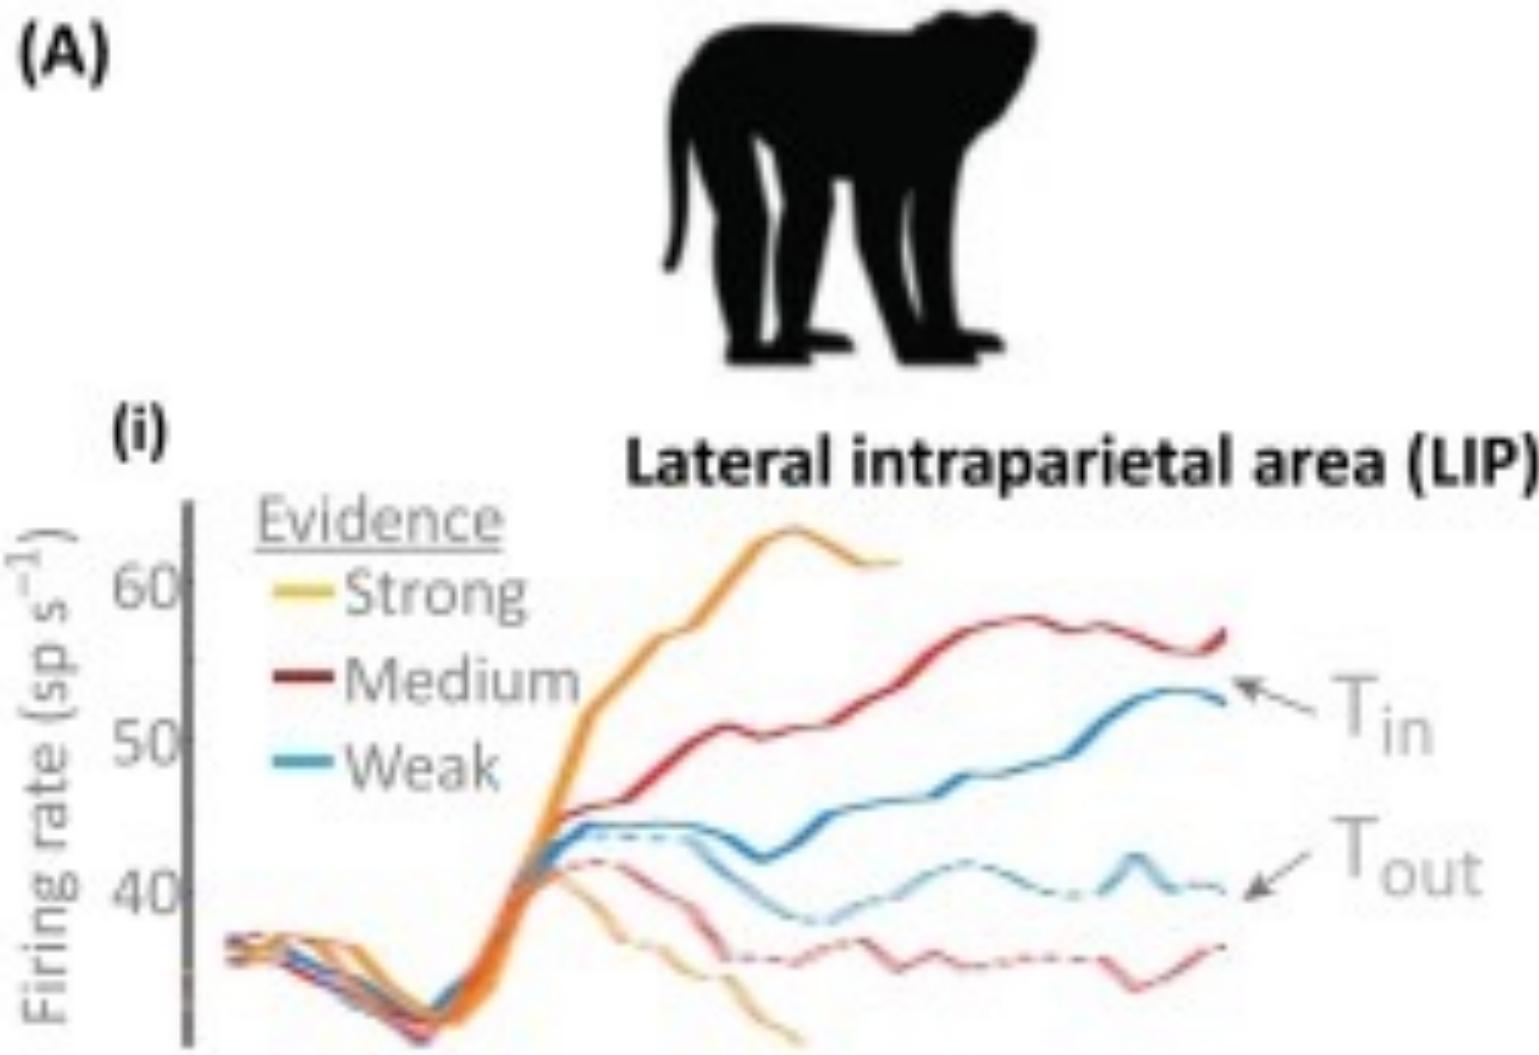

Brief aside ...
Neural basis of the DDM

Neural network implementation

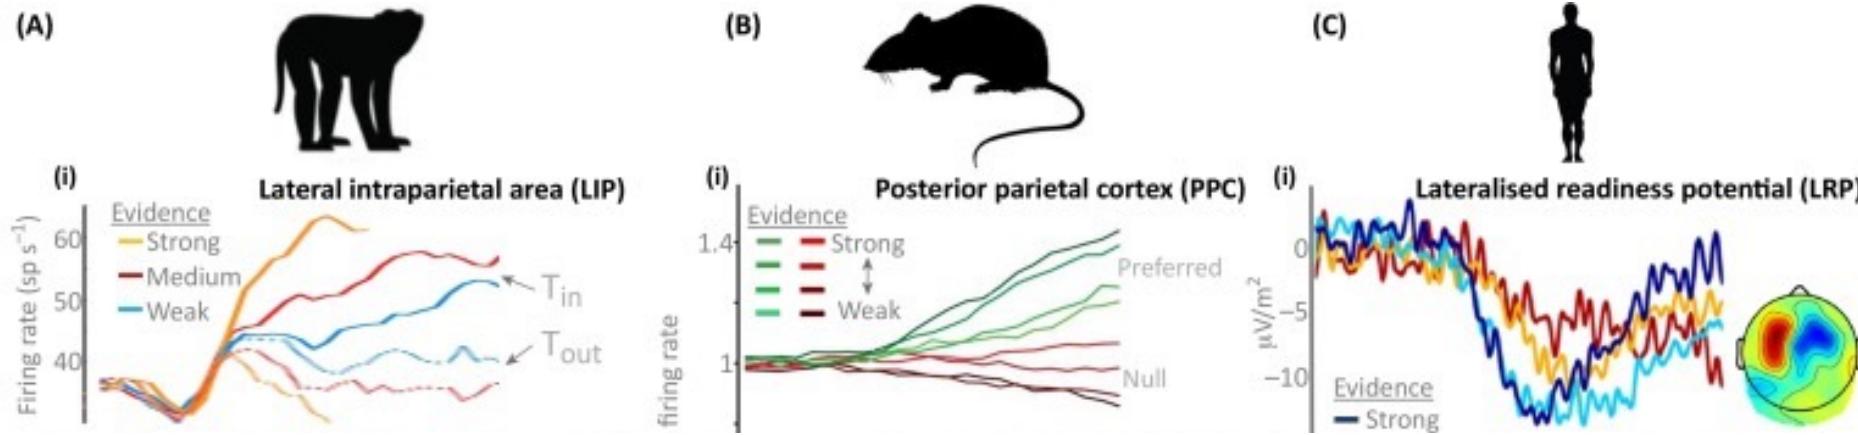

- Different ways of implementing DDM in a neural network
- Most have a similar structure, although underlying mathematics can be different

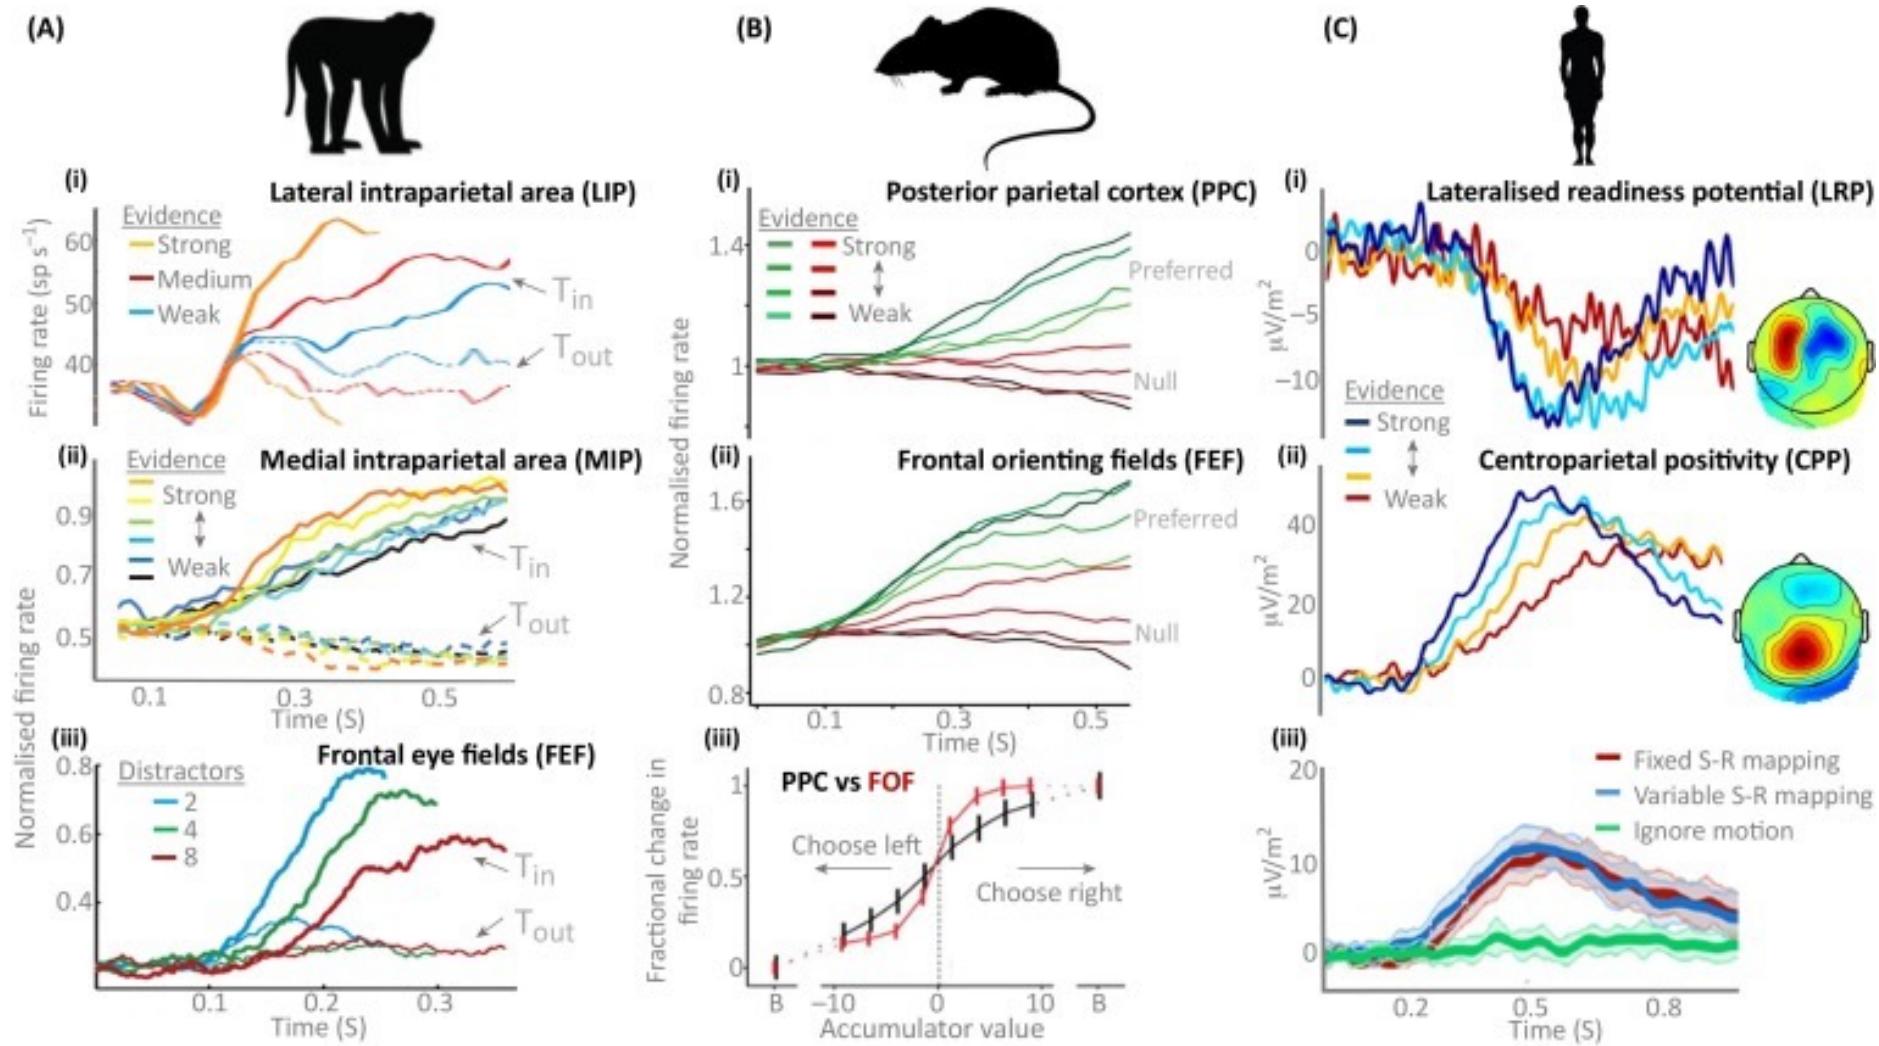

DDMs in the brain ...

DDMs in the brain ...

DDMs in the brain ...

Value-based drift diffusion model

Applying the drift diffusion model to value-based decisions

- Value-based decision implies having a value for different options
- Focus on two-choice case
- Choose between option 1 with value V_1 and option 2 with value V_2
- Simple way to connect to DDM is to set the drift rate proportional to the difference in value ...

$$A = k(V_2 - V_1) = k\Delta V$$

Value-based DDM – choices

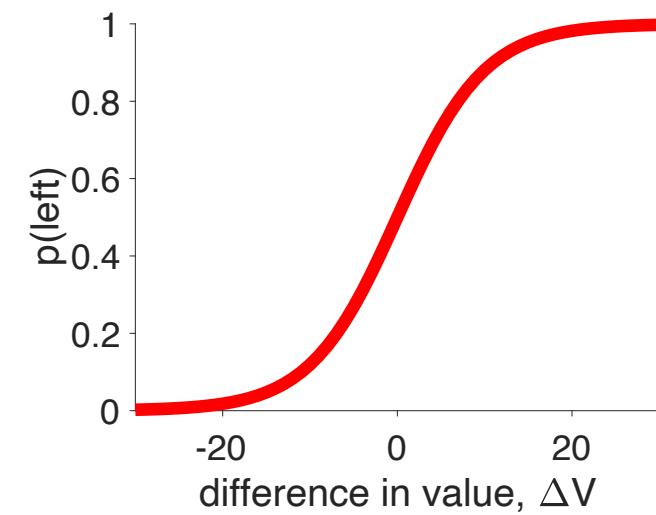

- Choice probabilities ...

$$p(\text{choice} = \text{left}) = \frac{1}{1 + \exp(2zk\Delta V)} - \frac{1 - \exp(-2x_0k\Delta V)}{\exp(2zk\Delta V) - \exp(-2x_0k\Delta V)}$$

- Special case when unbiased starting point, $x_0 = 0$

$$p(\text{choice} = \text{left}) = \frac{1}{1 + \exp(2zk\Delta V)}$$

- This is the **softmax choice probability!**

Softmax and the value-based DDM

- Compare with softmax equation ...

$$p(\text{choice} = \text{left}) = \frac{1}{1 + \exp(2zk\Delta V)}$$

$$p(\text{choice} = \text{left}) = \frac{1}{1 + \exp(\beta\Delta V)}$$

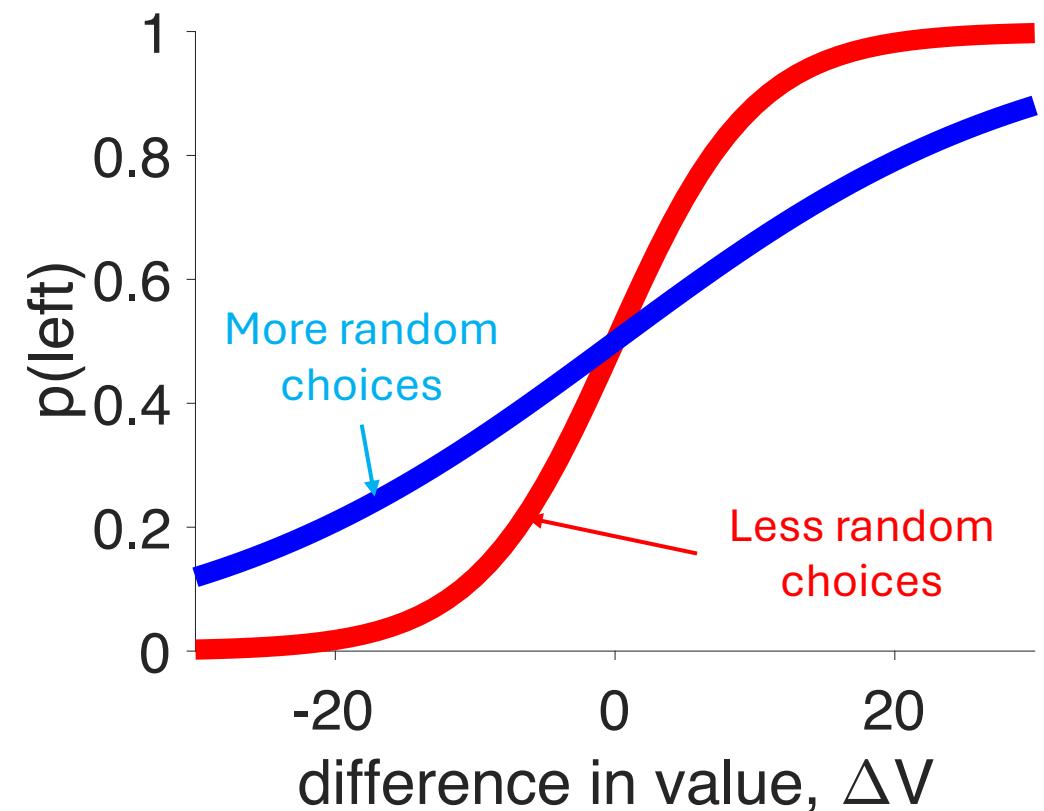

- Inverse temperature parameter of softmax is controlled by TWO DDM parameters

$$\beta = 2zk$$

- Threshold, z, and signal-to-noise ratio, k

Softmax and the value-based DDM

- More random choices can be generated by
 - Lower drift rate (signal-to-noise ratio), k
 - Lower threshold, z
- Different mechanisms – **cannot be distinguished by choices alone**

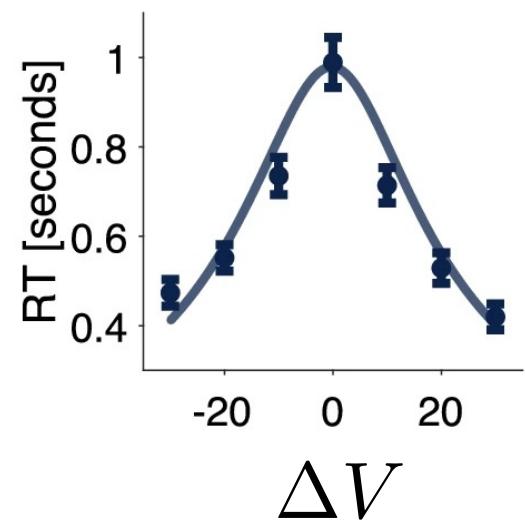

Value-based DDM – response times

- Response times

$$RT = T_0 + \frac{z}{\Delta V} \tanh(z\Delta V) + \frac{z}{\Delta V} \frac{2(1 - \exp(-2x_0\Delta V))}{\exp(2z\Delta V) - \exp(-2z\Delta V)} - x_0\Delta V$$

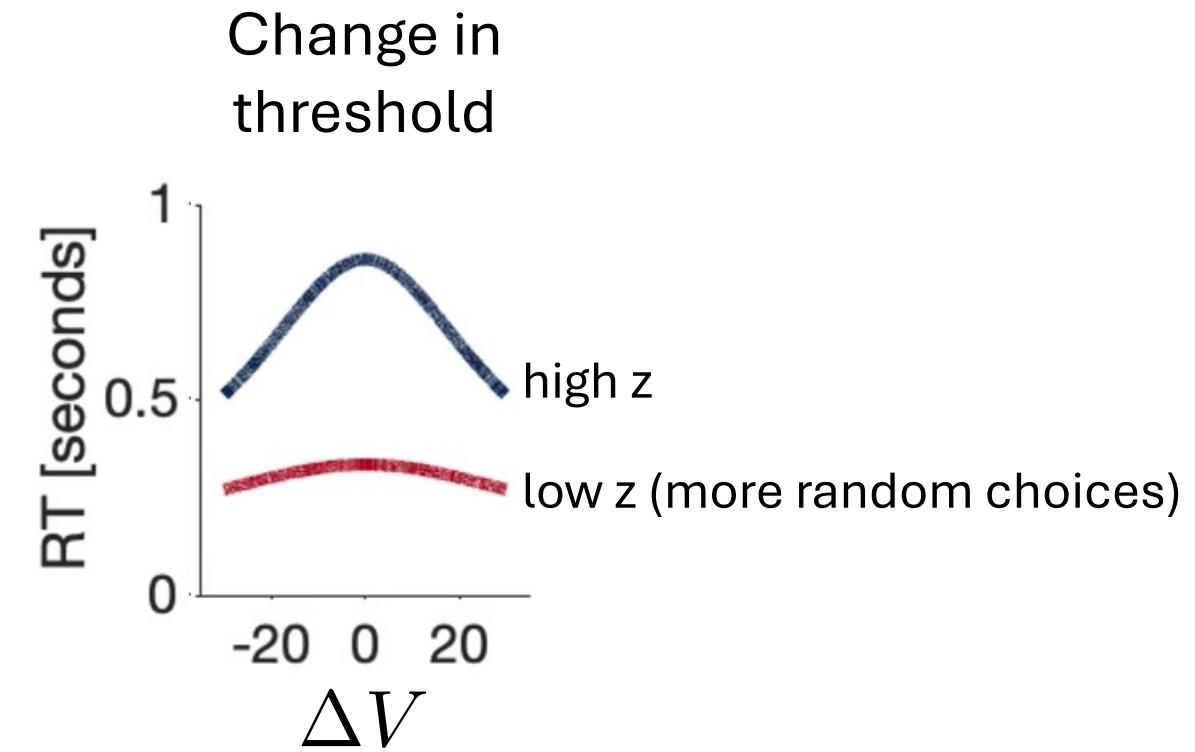

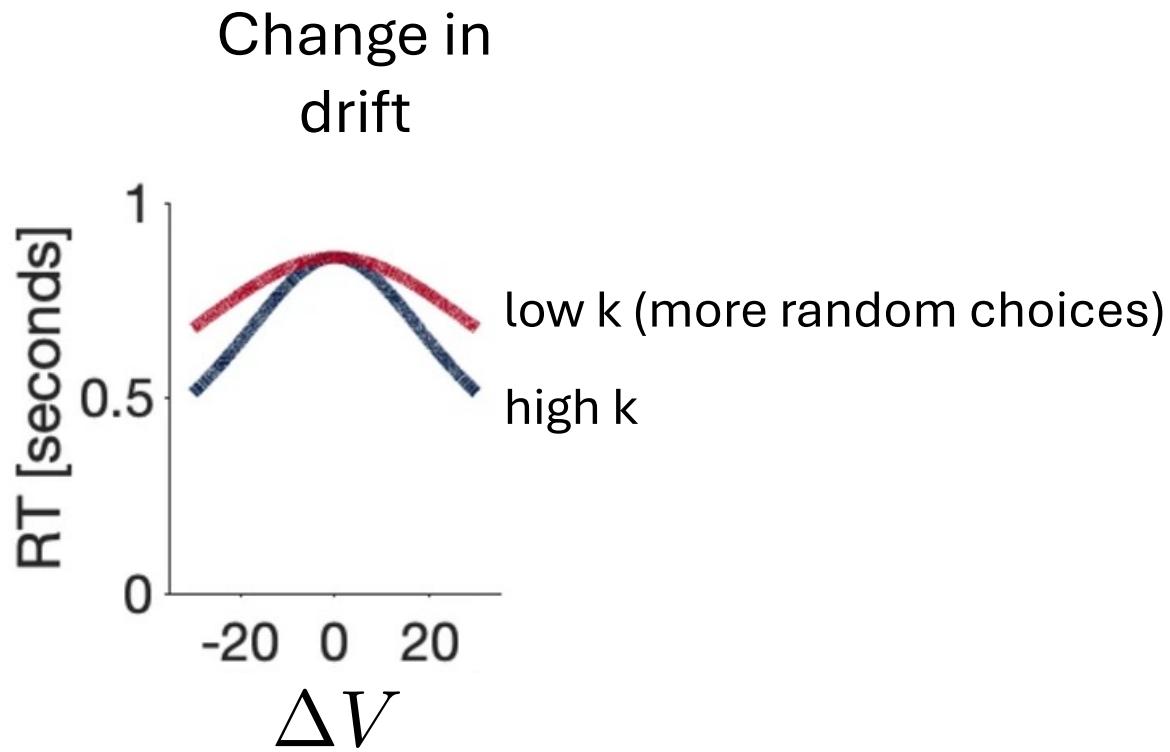

- Special case when unbiased starting point, $x_0 = 0$

$$RT = T_0 + \frac{z}{\Delta V} \tanh(z\Delta V)$$

Value-based DDM – response times

- Changes to drift and threshold ratio have opposite effects on response times ...

Value-based DDM

- Set drift rate proportional to difference in value between options
- Gives softmax choice probabilities when initial condition is 0
- Randomness in choice can be controlled by two difference mechanisms
 - Drift change
 - Threshold change
- These mechanisms can be distinguished using response times

Example: What drives random exploration?

Explore-exploit decisions

STARTERS

Pizza Bianca (White Pizza) ... \$5.50
Sprinkled with Parmesan Cheese, Oregano, and Olive Oil.

Mozzarella in Carozza \$6.50
Fried Mozzarella with Anchovies, Garlic and Cream Sauce.

Calzone \$5.50
Made fresh on the premises.

PASTA

Fettuccine Alfredo \$10.95
Egg Noodles in Cream Sauce and Parmesan Cheese.

Seafood Scampi \$16.95
Shrimp, scallops, squid sautéed in garlic, olive oil. Served on fresh linguine.

New Ravioli di Ricotta \$11.95
Pasta Stuffed with Ricotta and Parmesan Cheese. Served with Tomato Sauce.

Linguine Vegetariani \$13.00
Sautéed in butter with mushrooms, zucchini and red pepper.

PIZZA

10" 14"

Cheese and \$11.75 \$13.75
Tomato
based on the "Pines of Rome" classic

Fresh Herb \$14.75 \$16.95
a blend of herbs, topped with an olive oil & chèvre cheese

New Thai Chicken \$15.75 \$17.95
chicken marinated in a spicy peanut-ginger sesame sauce

Garden Veggie \$13.75 \$15.95
olives, onions, green peppers, & tomatoes

Greek Pizza \$14.75 \$16.75
mediterranean spiced grilled chicken & mozzarella

New The Works \$18.95 \$22.95
Canadian bacon, salami, pepperoni, sausage, beef, olives, pineapple, mushrooms, onions, green peppers, etc. etc.

Hawaiian BBQ \$16.75 \$18.95
fresh pineapple, BBQ chicken, & smoked gouda

The Horizon Task

explore

exploit

- Suppose you're leaving town tomorrow
 - Short horizon
- Suppose you're leaving town in a year
 - Long horizon
- The difference in behavior can quantify exploration

The Horizon Task

explore

exploit

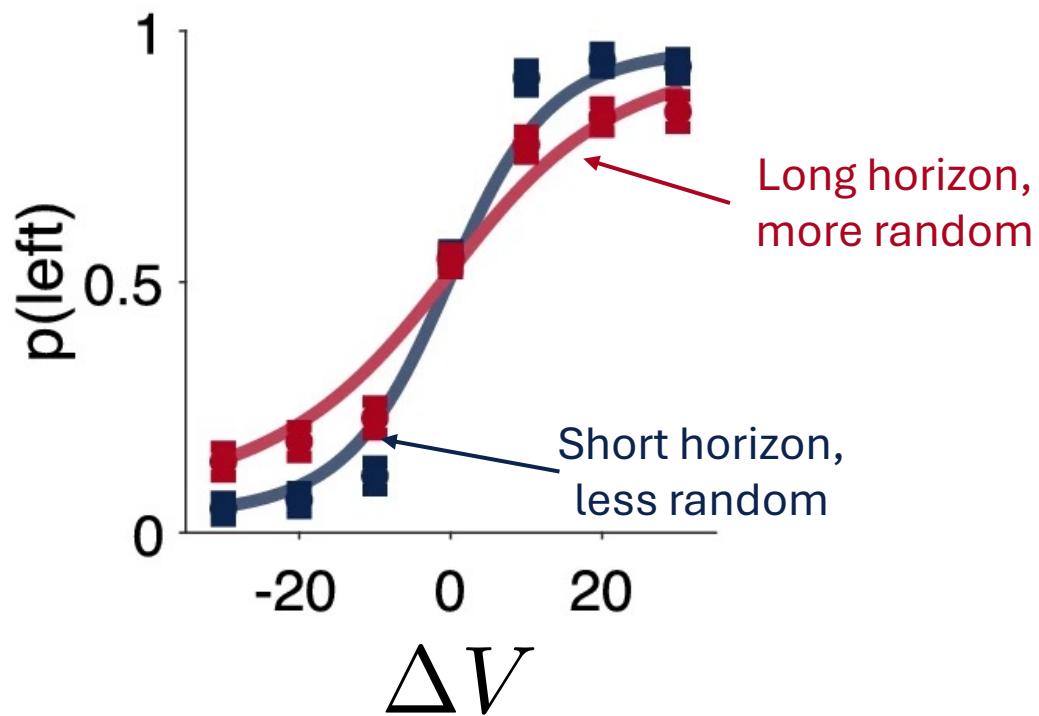

Two strategies for exploration

- Directed exploration
 - Bias choices towards more informative options
- Random exploration
 - Choose more randomly

Random exploration

- When it is valuable to explore, participants choose more randomly
- The slope of their choice curve is lower
 - The softmax parameter is smaller when it is more valuable to explore

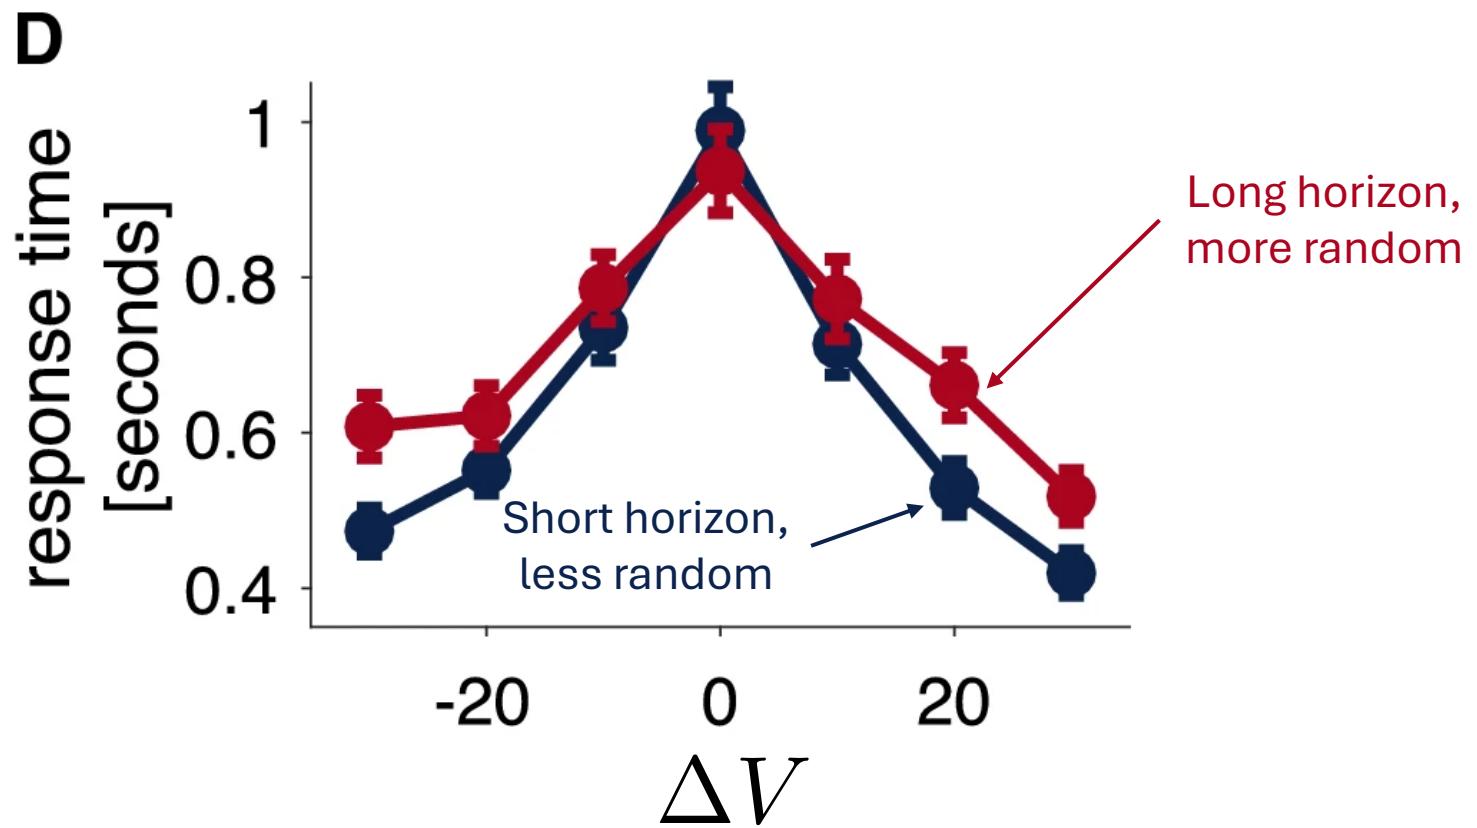

- BUT WHY?

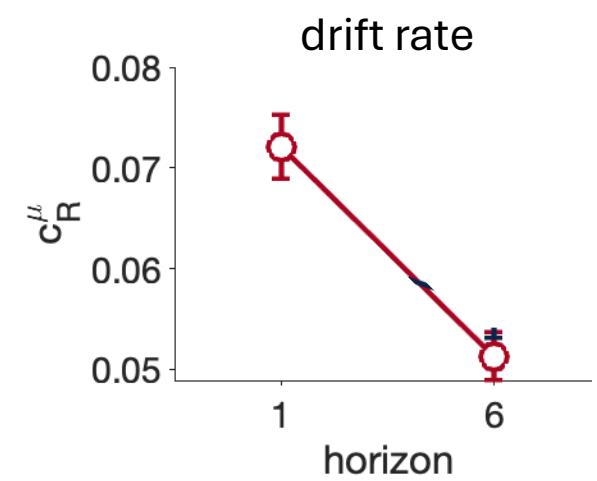

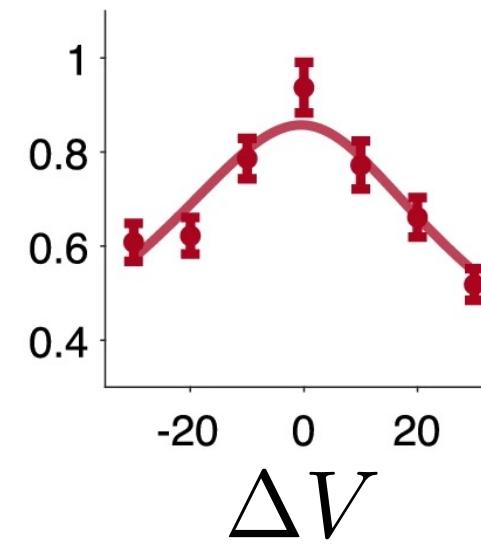

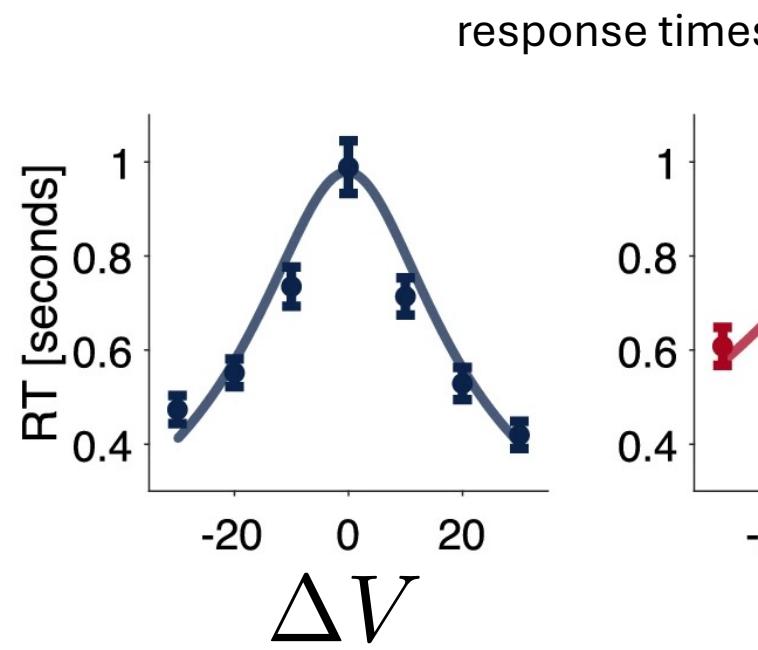

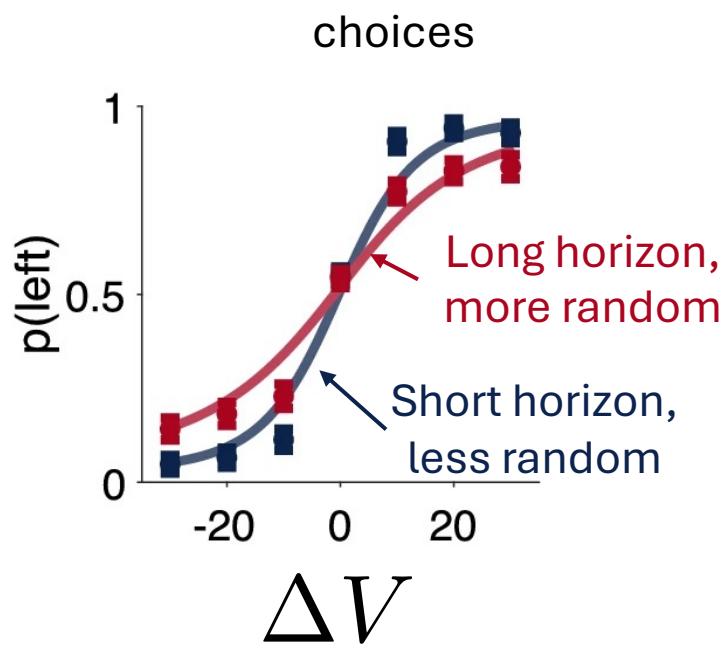

Two mechanisms for random exploration

- If decision is made using a drift diffusion process, then randomness can be modulated in two different ways ...
 - Reducing threshold
 - increases randomness, speeds up response times
 - Reducing drift rate
 - Increases randomness, slows down response times
- So ... do people speed up (\Rightarrow threshold change) or slow down (\Rightarrow drift change) when they are randomly exploring?

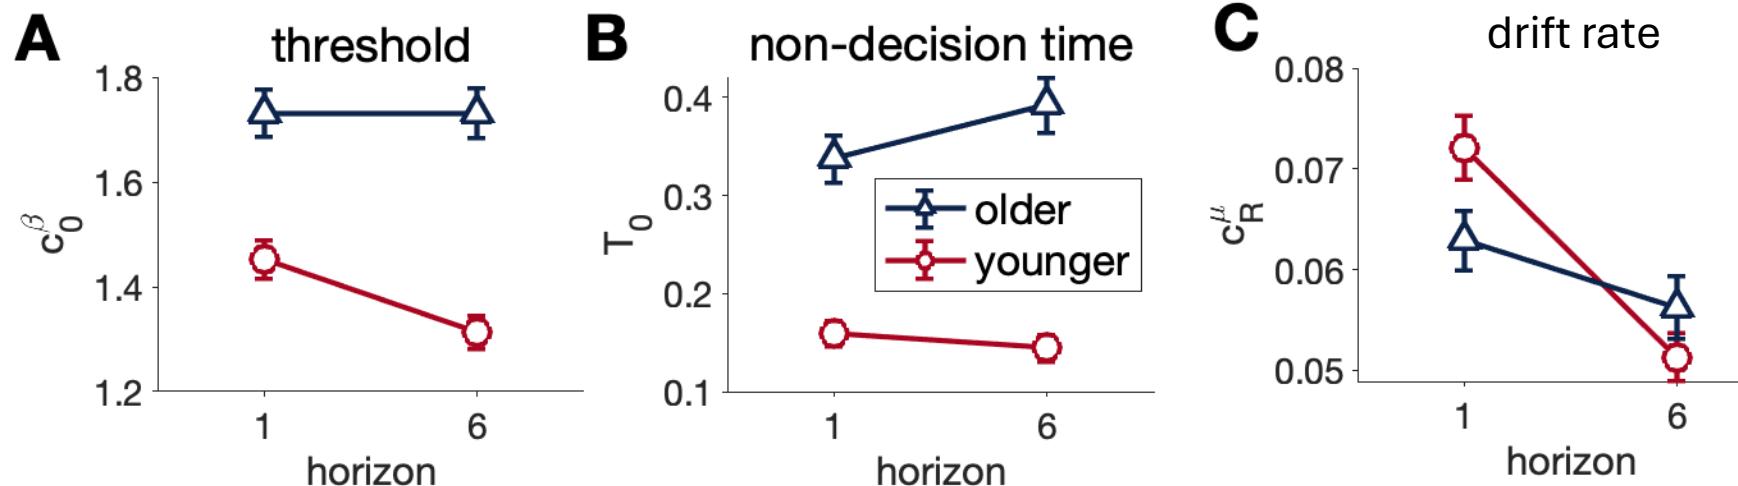

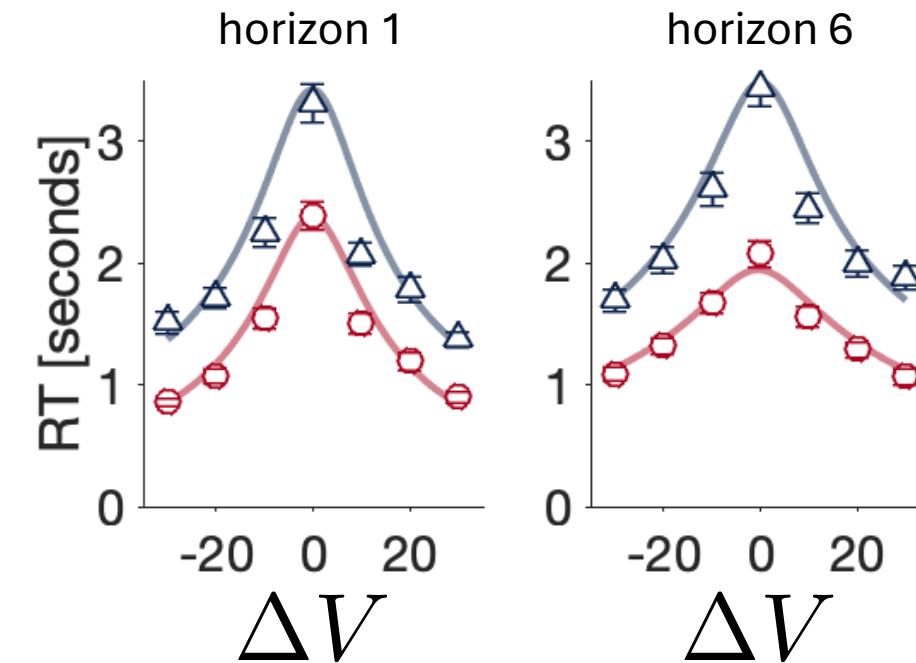

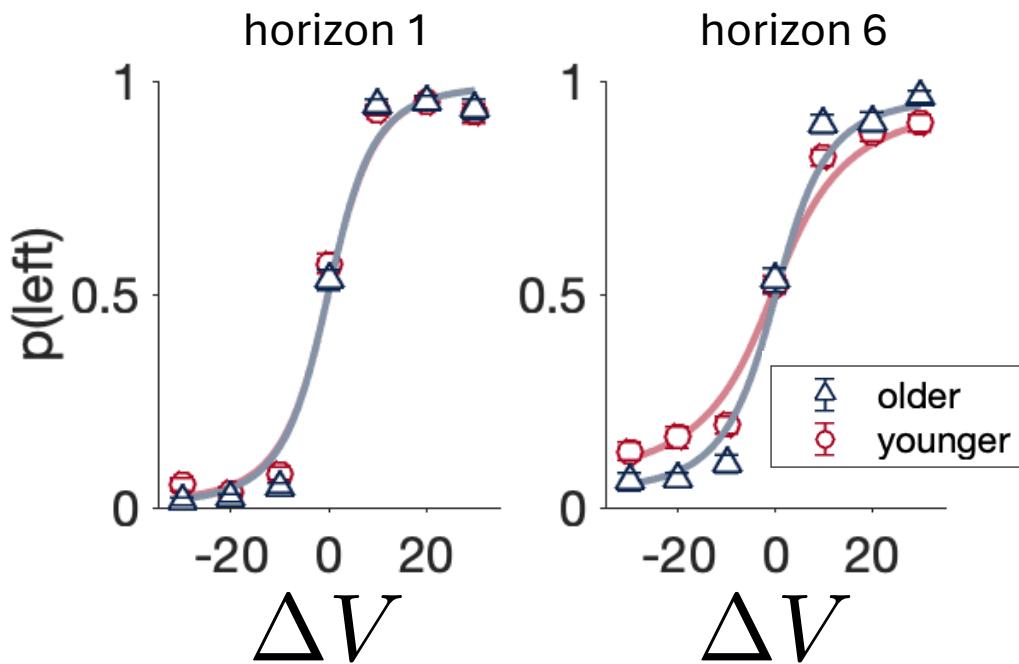

They slow down => drift rate change (mostly)

Be more precise by fitting the DDM ...

What about aging?

DDM and random exploration

- Random exploration is primarily driven by a change in drift rate, not a change in response threshold
 - Suggests a signal-to-noise mechanism
 - But can't distinguish whether it's a change in signal, noise, or both using the DDM, need neural data to go further
- Same pattern is seen in older adults
- But older adults have
 - Higher threshold
 - Longer non-decision time
 - Less modulation of drift rate for exploration
- Amounts to slower responses and less random exploration in older adults

Summary

Drift diffusion model

- Mechanistic model of decision formation
 - Can be connected to neural implementation
- Models choices and response times
- Can be applied to value-based decisions
 - Softmax is a special case
- Allows for better characterization of individual differences and mechanistic answers about the nature of choice variability

Limitations of the DDM

- Main formulation only deals with two-alternative forced choice situations
 - Ignores multi-alternative models
 - Extensions exist
- Assumption that parameters are constant over time
 - Relaxing this constraint can make things a lot more complicated
- Assumption that decision is made quickly in one process

Beware different parameterizations!

- There are different parameterizations of the drift diffusion model
 - The same symbol can mean very different things depending on who's writing the paper!
 - E.g. z for threshold vs z for starting point
